OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., January 3, 1883.

No. 1.

THE AMERICAN
BEE JOURNAL

PUBLISHED BY

THOMAS C. NEWMAN,
EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.

Weekly, \$2 a year; Monthly, \$1.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago Post Office as
Second Class Matter.

The Oldest Bee Association.

In an editorial on the benefits of apianian exhibits at fairs, in the BEE JOURNAL for Dec. 13, 1882, we remarked as follows:

The Michigan State Bee-Keepers' Association is the oldest in America, and we are pleased to say that it has been among the first to realize the importance of appointing a committee for the purpose of conferring with the officers of the State Fair, relative to giving the bee-keeping interests their due share of attention and prominence at the Fair.

Mr. E. Rood, ex-President of the Michigan State Bee-Keepers' Association, sends us the following criticism for publication:

MR. NEWMAN: I see, in the last two numbers of the BEE JOURNAL, that Michigan is credited with having organized the first bee convention in the United States. This is a mistake. A convention of considerable numbers of bee-men was held at Cleveland, Ohio, in March, 1860, at which Prof. J. P. Kurtland was President. Mr. L. L. Langstroth and others were present; the first question discussed was on wintering bees. Two subsequent conventions, at least, were held at Cleveland in 1861. The first Michigan convention was held a few years after, and was suggested and gotten up by the late A. F. Moon, as was also the American Bee-Keepers' Convention, of which he was the first President. It was held at Indianapolis, Ind. See Volume 1, pp. 67, 116, 281, 282 of the AMERICAN BEE JOURNAL, 1861. For history and date of first Michigan convention, I respectfully refer you to Prof. A. J. Cook, of Lansing, Mich. E. ROOD.
St. Paul, Minn., Dec. 26, 1882.

Mr. Rood makes the mistake of supposing that we said that the Michigan society was the *first* bee convention.

We well knew that it was not the *first* bee convention held in America; but we reiterate that it is the *oldest* Association. The convention in Cleveland was a transient affair, convening a few times and then *dying* entirely, while the "Michigan State Association" has just held its *seventeenth* regular annual meeting, and is the *oldest* Association; the North-Eastern (New York) comes next, which holds its thirteenth annual meeting at Syracuse next Tuesday, Wednesday and Thursday, Jan. 9-11, 1883. We thank Mr. Rood for the courtesy of calling attention to the matter, but the error is entirely his own—he *meant* one thing, while we said another.

Our thanks are due to those who have renewed their subscriptions for the coming year—and they have so generally done this, that we believe our efforts to publish an acceptable weekly bee paper are appreciated, and our labors are rewarded. Our correspondents as well as advertisers also have our thanks.

The *Indiana Farmer* begins its new volume with a quarto size, which is far more convenient for reference and preservation. It is an able and well-conducted paper for the farm, and has a good bee department.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but should be written on separate pieces of paper.

Gathering the Statistics.

A committee was appointed by the "North American Bee-Keepers' Society," at its late meeting in Cincinnati, Ohio, for the purpose of securing statistical information relative to bee culture in North America. The members of this committee had a meeting last month, and elected Dr. C. C. Miller, chairman, and authorized him to issue a call for information through all the bee papers of America, and directed him to receive, assort and tabulate them, and then to offer the Tabulated Statistical Table for publication, in all the papers devoted to apiculture in particular, and agriculture in general, as well as to present that table and report to the next meeting of the North American Bee-Keepers' Society, to be held at Toronto, Canada, next fall. In accordance with these instructions, Dr. Miller has issued the following notice, and asked the editors of all the bee papers to publish it, simultaneously, in the first issue of January, 1883:

MR. EDITOR:—At the last meeting of the North American Bee-Keepers' Society, a committee was appointed to obtain statistics relating to bee culture. Upon consultation, the committee have decided to ask, through the various papers devoted to the interests of bee culture, for information directly from the bee-keepers themselves. Will you, therefore, please request each bee-keeper to report his name, postoffice, State, the number of colonies he had in the fall of 1881, the number in spring of 1882, the number in fall of 1882, the number of pounds comb honey taken in 1882, the number of pounds extracted, and the number of pounds of beeswax. Let it be written on a postal card, like the following:

F. Torrens,
East Liberty, Pa.
21 colonies, fall, 1881.
18 colonies, spring, 1882.
25 colonies, fall, 1882.
400 lbs. comb honey.
300 lbs. extracted.
3 lbs. beeswax.

No date is needed; send the postal to Dr. C. C. Miller, Marengo, Ill., and as soon as they can be obtained, the results will be given through the papers making this request.

Let each bee-keeper send in the report of any other bee-keeper who does not send in his own report.

C. C. MILLER,
Chairman Statistical Committee.

We would respectfully request every reader of this notice to sit down at once and send a postal card to Dr. Miller, Marengo, Ill., and give the six items he requests, as above. By doing this small share in the work every one will be benefitting him or herself, as

well as aiding the cause of bee culture generally throughout the country. Please do not think because you have reported to some bee paper, that such will do in place of this, but stop right here, before reading any further, and

✂ WRITE TO DR. MILLER. ✂

Now, having written the postal card as requested, let us talk the matter of statistics over a little. Here is a letter from Mr. H. L. Jeffrey, Vice President of the N. A. B. K. Society for the State of Connecticut, who wants to have a chat with you upon

THOSE STATISTICS.

I have been deeply interested of late in the articles on obtaining a correct statistical report of bees, honey and beeswax in the United States. I most heartily wish it may be obtained, though I very much doubt that it will be, during 1883.

While reading the letter from Prof. Cook, ex-President of the North American Bee-Keepers' Society, I could not help smiling to think how much help could or would be obtained from the town or State supervisors, as I have had a slight experience in trying to obtain any amount of information from that source. During the census taking, I found just one willing to give any aid out of over thirty that I had conversation with, and he was a bee-keeper. Through him I obtained, as we afterwards found out, just five-sixths of the number of colonies in his town.

In the year 1880, if I remember correctly, you, Mr. Editor, sent me a card asking an effort to obtain, as near as possible, the statistics of Connecticut. Ever since then I have used every available means to obtain it, and I find that it is next to an impossibility to find out very much.

In the first place, the number of colonies in the spring should be stated.

2. The increase, the amount of surplus honey, and the amount of beeswax, etc.

3. The number of colonies to be put into winter quarters, saying nothing of the hive used, the method of wintering, etc.

Now comes the trouble. There are so many box-hive men to be looked up, whose separate productions for the market supply may be compared with one mill to a dollar, though it should be known to make the whole complete, and their wax product is proportionately greater than that of the practical apiarist.

In order to obtain the information in my last annual report to the North American Bee-Keepers' Association, I have worked for three years, and I honestly do not believe it is anywhere near correct, though I worked faithfully for it, and used every means in my power, and my memoranda shows it cost nearly \$100, to say nothing of the time spent in writing or visiting bee-keepers, or the amount used for postage on letters or cards I received from parties furnishing me with information.

Scarcely any one ever thinks of the magnitude of such an undertaking, except those having tried it, and, worse than all, is the amount of fault-finding there is to withstand from those thinking they could have done better, though, in reality, the hardest amount of work they do is with their tongue.

Mr. J. S. Terrill's plan is quite worthy of a trial if the vice-presidents have either ambition or curiosity enough about them to push it through; and there is another trouble, if they have too much push they will not get any information, because it takes time and some trouble to make out even a small report. The greatest trouble is to try to get a report within a stated time, because no man will do anything till he gets ready, and the more you drive the more he holds back; nevertheless, it can be worked at, year after year, until a nearly correct statistical table will be the result.

Let the Committee on Statistics appoint a man in each State, giving him a specimen blank; furnish him a list of all the bee-keepers, and allow him three months in which to do his best, then call for a report; then call for another final report, in time for the National Convention. I know that a fair result can be obtained by that plan. Nearly every State has either an agricultural paper or a principal paper of some sort, and its columns can be used by some one to a very satisfactory result. Write a few articles for it, then make a call through its columns, and he will hear from more than he thinks; then, two or three more articles, another call and another response; each time he will obtain a wider field. I have tried this plan and I find it is better than anything except a regular, thorough canvass. Try not only the papers, but solicit aid of all the farmers' clubs and the agricultural societies. H. L. JEFFREY.

Woodbury, Conn., Dec. 23, 1882.

The reader will please notice the fact that Mr. Jeffrey has worked for three years and spent nearly \$100 in money, in his endeavor to get the correct statistics of his State on bees and honey. Now, shall we ask another favor of you? Of every bee-keeper you can obtain an interview with, no matter whether he has 5 or 500 colonies of bees, just make a memorandum of his name, post office and State (so that it may be classified), and then send to Dr. Miller a postal card containing the reports, from your memorandum book, of the season's work of every one who has not himself already reported. This is but a trifling matter, but will tell wonderfully on the general result. Instead of costing you \$100, as it has Mr. Jeffrey, it will cost you but a few cents, and you will be fully rewarded in the general results which will certainly follow the attainment of correct figures concerning the honey crop of America.

Prof. Cook very aptly remarks that "the magnitude of the business once known, it will be better appreciated as one of the important industries of the country." But few can fail to recognize the importance of full and accurate statistics of the present condition of Apiculture in the United States, both as to the number of colonies of bees and the honey product, and we hope, as a result of this endeavor, to obtain them. If we fail, the failure will be justly charged to the bee-keepers themselves throughout the country.

The International Fair at Hamburg.

From Washington we have the following in reference to the General Stock Fair at Hamburg, Germany. We should very much regret it, if the American bee-keeping interests are not fully and creditably represented. A dispatch from Washington, a few days ago, published in the daily papers, is as follows:

The assistant secretary of state is just in receipt from the United States consulate at Hamburg of full information in regard to an international exhibition of domestic animals, fish, etc., to be held at Hamburg in July, 1883.

The committee of this exhibition are exceedingly desirous of calling the attention of the people of the United States to this matter, and solicit their participation in the exhibition. The committee having charge of the exhibition is composed of the leading and most distinguished citizens of Hamburg, together with representative men from other countries. The special programme will have many novel features. The exhibition will begin on July 3, 1883, and will be closed on July 11.

The following departments will be fully represented: Horses and mules, cattle, sheep, swine, bees, with appliances for their keep and culture, with their products; fish and poultry, stalls and other places for the keeping of animals, as well as machinery and implements directly connected with the breeding, keeping, or culture of domesticated animals, and lastly, scientific researches and results, with the literature relative to the breeding of animals. For each of these sections there will be a special committee acting under the order of the general committee and the board of general directors.

All applications for space or place must be received by Jan. 30, 1883. As no duties exist in the district of the free city of Hamburg there are no custom-house complications. The prizes to be awarded in the several sections will consist of cash prizes, medals, certificates of merit and various honorary prizes. Cash prizes may be exchanged for articles of silver of an equivalent value. The commit-

tee is composed of the following persons: Albertus von Ohlendorf, president; Syndic Dr. Leo, vice president; Consul General Emile Notting, treasurer, and Richard Seeleman, secretary. The committee have made arrangements with the Hamburg-American Packet company for special reduced rates for the transportation of animals, etc., from New York to Hamburg, and also for their return to New York. C. B. Richard & Co. are the agents at New York.

Bee-Keeping in the South.

The following is a very reasonable article, which we notice in *The South*, and will be read with interest by those who contemplate removing their bees to some southern climate, during the present winter or coming spring:

It is claimed that honey is one of the most healthful sweets that can be found. As the honey bees feed on the pure juices of healthy plants, it is clear that the honey must partake of the quality of the blossoms from which it is extracted. The sugar in honey is of a highly nutritive character. It is a sweet of rare purity, and it has been regarded with peculiar favor from the remotest antiquity.

That the South is highly adapted to bee-keeping is evident from the natural condition of the country. The climate is promotive of rare exuberance of vegetation and of a flora varied, rich, and abundant. In the South the bees find not only this abundance from which to gather delicious sweets, but there are many plants, shrubs, and trees, such as basswood, poplar, persimmon, holly, black gum, blackberry, wild cherry, etc. In addition to these there are numerous honey-producing perennials.

Again, the season of labor is much longer than at the North. Neither does the bee suffer from the severity of the weather to the same extent as at the North. The economic aspects of the subject are largely in favor of the South as a place for the successful pursuit of the business.

In all sections of the South bee-keeping obtains. A Florida bee-keeper states that he started the season of 1881 with 35 colonies, which increased during the year to 86. During the same season he took from them 6,500 lbs. of honey. He attributes his success more to the natural advantages of the country than to any skill on his own part.

To insure success, bee-keeping requires intelligent attention and aptitude for the business. Those who undertake it without applying the proper means are likely to fail in this pursuit as in others. Theoretical knowledge is valuable, but practice is essential to a true comprehension and to the best results. The bee is endowed with wonderful instincts, the study of which is replete with interest. While reaping large profits from the pursuit, the bee-keeper may, at the same time, acquire a store of knowledge of the mysteries of nature.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., January 1, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The supply of extracted honey is fully up to the demand. My quotations are: 7c. for dark and 9c. for light, delivered here.

BEESWAX—It is quite scarce. I am paying 27c. for good yellow wax, on arrival; dark and off colors, 17c@22c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand is good for extracted in barrels as well as in glass jars and tin buckets; arrivals are fair. The demand is fair for comb honey, which, however, is not cheap enough to make trade lively. Extracted brings 7c@10c. on arrival; comb honey, 14c@20c.

BEESWAX—Is scarce and brings 20c@27c. on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey does not keep pace with the receipts. There is a large surplus on this market at present, and prices are from 2 to 3c. lower than last month.

We quote: white comb honey, in 16@21 lb. sections, 17c@19c. Dark comb honey, hardly any demand. It is held at 12c@15c. Extracted—White brings from 9c@10c.; dark, 8c@9c.; kegs, half-barrels and casks bring about same price.

BEESWAX—Choice Yellow, 30c.; dark to medium, 18c@25c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—No business worthy of note is reported. Offerings of dark honey, either comb or extracted, are neglected.

White comb, 17c@20c.; dark to good, 11c@13c.; extracted, choice to extra white, 8c@9c.; dark and candied, 7c@8c.

BEESWAX—We quote 25c@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull. Comb, at 16c. for large or hard to 19c@20c. for choice bright in small packages; extracted at 8c@9c.; strained, 6c@7c.; choice, in smaller quantities, brings more.

BEESWAX—Prime bright steady at 27c@28c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Has changed in price a very little, we find it necessary to sell all grades about 1 cent per lb. less. Best white, in 1 lb. sections, 20c@21c. per pound; in 2 lb. sections, 18c@20c. Extracted is very dull indeed, hardly any sale.

BEESWAX—Scarce, 26c@30c.

A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—There is only a moderate supply of choice to fancy white clover honey, and prices are still held firmly, though the demand is not large. Buckwheat and extracted honey continue slow.

We quote: White clover, first quality, 1 lb. boxes, 25c.; 2 lb. boxes, 23c@25c.; buckwheat, 1 lb. boxes, 20c.; 2 lb. boxes, 16c. Extracted, white, 12c@13c.; dark, 9c@10c.

BEESWAX—The supply has been light and prime lots held a shade higher.

Western pure, 30c@31c.; southern, pure, 31c@32c.

D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1 lb. sections at 30c.; 1 lb. sections, 22c@25c.; 2 lb. sections, 20c@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—30c.

CROCKER & BLAKE, 57 Chatham Street.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Local Convention Directory.

1883. *Time and Place of Meeting.*

- Jan. 2-4.—Eastern N. Y., at Albany, N. Y.
E. Quakenbush, Sec., Barnerville, N. Y.
- 9.—Cortland Union, at Cortland, N. Y.
M. C. Bean, Sec., McGrawville, N. Y.
- 9.—Ohio State, at Columbus, Ohio.
D. Spear, Sec., Cardington, Ohio.
- 9-11, Northeastern, at Syracuse, N. Y.
G. W. House, Fayetteville, N. Y.
- 10, 11.—Indiana State, at Indianapolis, Ind.
Dr. J. H. O'Rear, Pres.
- 11, Nebraska State, at Wahoo, Neb.
Geo. M. Hawley, Sec.
- 16.—N. W. Ill. and S. W. Wis. at Freeport.
J. Stewart, Sec.
- 18, Champlain Valley, at Middleburg, Vt.
T. Brookins, Sec.
- 19, 20.—Mahoning Valley, at Berlin Centre, O.
L. Carson, Pres.
- 20.—S. W. Mich., at Ann Arbor.
G. J. Pease, Sec., Ann Arbor.
- Feb. 3.—Northern Ohio, at Norwalk, O.
- 8.—Maine State, at Dexter.
Wm. Hoyt, Sec.
- 14, 15.—N. E. Ohio and N. W. Pa., at Andover.
C. T. Leonard, Sec.
- April 5.—Utah, at Salt Lake City.
E. Stevenson, Sec.
- 17, 18.—Texas State, at McKinney.
Wm. R. Howard, Sec.
- May 11.—Iowa Central, at Winterset.
J. E. Pryor, Sec.
- , —Texas State Convention, at McKinney.
Dr. W. R. Howard, Sec.
- Oct. 17, 18.—Northwestern, at Chicago, Ill.
Thomas G. Newman, Sec.
- 9, 10.—Northern Mich. at Sheridan, Mich.
O. R. Goodman, Sec., Carleton City, Mich.
- Dec. 5-6, Michigan State, at Flint.
H. D. Cutting, Sec., Union, Mich.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Convention Notices.

☞ The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883.
C. T. LEONARD, Sec.

☞ The annual meeting of the Cortland Union Bee-keepers' Association will be held in Cortland, N. Y., on Tuesday, Jan. 9, 1883.
M. C. BEAN, Sec.
McGrawville, N. Y.

☞ The annual meeting of the Champlain Valley Bee-Keepers' Association will be held at Middleburg, Vt., on Thursday, January 18, 1883, at 10 a. m.
T. BROOKINS, Sec.

☞ The Northeastern Bee-Keepers' Association will hold their thirteenth Annual Convention in the City Hall, at Syracuse, N. Y., on the 9th, 10th and 11th days of January, 1883.

Business of great value to every bee-keeper in the State will be brought before the meeting. Every member is requested to attend and bring their friends, that all may be benefited by the action there taken.

The question drawer will be opened each day, and questions answered and discussed. All are invited to send questions. Appropriate diplomas will be awarded to successful exhibitors of implements, etc. Let all attend.

GEO. W. HOUSE, Sec.

☞ The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

The following committees have been appointed, and the programme arranged for the next meeting, by the executive committee; viz: on Resolutions; Apian Supplies and Exhibits; Subjects for Discussion; and Arrangements, to receive and entertain those in attendance from abroad.

Programme.—President's Address. Subject—State and National Conventions.

Subjects for general discussion:

Essays.—The "Coming bee," W. H. Andrews. Honey plants, Native Horsemints, different varieties, Wm. R. Howard. "Extracted vs. Comb Honey," W. K. Marshall, D. D. "Bee-Moth," W. H. Andrews. "The Queen Bee, her nature and habits, Wm. R. Howard. "The different races of bees in America; their relative value to apiculture," W. K. Marshall, D. D.

Other essays are promised, and a general good time is anticipated. Ample arrangements are made to accommodate those from a distance. Those wishing to place anything on exhibition or correspond with the committee of arrangements, will be promptly attended to, by addressing, W. H. Andrews, President, McKinney, Collin Co., Texas. All other correspondence to the Secretary. We would be pleased to have any one propound questions of interest for discussion, as we have found great interest, as well as valuable information gained by the discussion of questions contributed to our "Question Box."

WM. R. HOWARD, Sec.
Kingston, Texas.

☞ The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in Temperance Hall, Freeport, Stephenson county, Ill., on January 16 and 17, 1883.

JONATHAN STEWART, Sec.
Rock City, Ill.

☞ The Eastern New York Bee-Keepers' Union will hold their 11th Semi-Annual Convention on Tuesday, Wednesday and Thursday, January 2nd, 3d, and 4th, 1883, at the State Agricultural Rooms, State Street, Albany, at 10 o'clock, a. m. All interested in bees are invited to attend.

C. QUACKENBUSH, Sec.
W. L. TENNANT, Pres.

☞ The Nebraska State Bee-Keepers' Association, will hold its annual session in Wahoo, Saunders county, Neb., commencing Thursday, Jan. 11th, 1883. Arrangements have been made with the railroads to secure 1 $\frac{1}{2}$ fare for the round trip. The Saunders county Bee-Keepers' Association will furnish entertainment free to all visiting apiarists. Bee-keepers from neighboring States will be welcomed.

T. L. VONDORN, Pres.
GEO. M. HAWLEY, Sec.

☞ The Southeastern Michigan Bee-Keepers' Association will hold their annual meeting in the courthouse at Ann Arbor, Jan. 20, 1883. All are invited. H. D. CUTTING, Pres.
G. J. PEASE, Sec., Ann Arbor.

☞ The Ohio State Bee-Keepers' Association will meet in Columbus, in the rooms of the *Ohio State Journal*, on Tuesday and Wednesday, Jan. 9 and 10, 1883. A full attendance of members, and all interested in bee-culture, is requested, as matters of interest and importance will be discussed.

Dr. H. BESSE, Delaware, O., Pres.
DANIEL SPEAR, Cardington, O., Sec.

☞ The annual meeting of the Mahoning Valley Bee-keepers' Association will be held at Berlin Center, Mahoning Co., O., in the town hall on Friday and Saturday the 19th and 20th of January, 1883. All bee-keepers are invited to attend and send essays, papers, implements, or any thing of interest to the fraternity. A full attendance is requested of all who are interested. In fact, the meetings will be so interesting that you cannot afford to miss them. We expect a lecturer from abroad on the evening of the 19th. L. CARSON, Pres.

☞ The Indiana State Bee-Keepers' Association will hold its annual meeting at Indianapolis, Ind., on Jan. 10 and 11, 1883. All are invited.
Dr. J. H. O'REAR, Pres.

☞ The quarterly meeting of the Marshall County Bee-Keepers' Association will meet in Marshalltown, Iowa, on Saturday, Jan. 6, 1883, at the Sheriff's office, in the Court House, at 10:30 a. m. The subject for discussion being "Winter and Spring Care."
J. W. SANDERS, Sec.

Subscription Credits.—After sending subscriptions to this office, we would respectfully ask every one to look at the label on the wrapper of the next two papers, and there they will find the credit indicated thus: Those who have paid for the first six months of next year will find "June 83" after their names. Those who have paid for the whole year will find "Dec. 83" on their papers. The credit runs to the end of the month indicated. If the mark is "Dec. 82," it means that the subscription is paid until the end of the present year. Please remember that the credit given on this label is a sufficient notification of subscriptions due and receipt for payments made. If not so indicated within two weeks after sending money to us, you may be sure something is wrong, and should write to us about it. It will save annoyance and trouble if our subscribers will give this matter due attention.

For the American Bee Journal.

One-Half Pound Sections for Honey.

JAMES HEDDON.

For sometime Boston honey dealers have been quoting half-pound sections of honey at prices about 5 cents per pound higher than those quoted for the one-pound package. These figures have set hundreds of producers to thinking about another change, wishing, as all progressive men do, to "keep abreast of the times," and reap the profits that always accrue by so doing. They also do not forget that changes cost money, patience and time, and they dislike to step out from the beaten path, without some sort of certainty that they are moving in the right direction. At our late Michigan State convention this subject was taken up and discussed at considerable length. I was reported as saying that I was intending to adopt the half-pound size. This was a mistake. What I said was that my neighbor bee-keeper (Mr. W. H. Shirley), to whom I sold my Glenwood apiary, finds 2-lb sections too large, and thinks of jumping the whole distance at one leap, and going, not to the one-pound, but to the half-pound sections; and that we had been holding private conventions of two, over the matter for some considerable time.

Since the report appeared I have received several communications regarding my opinion about the matter. It has been said that "a man will give his opinion when he will not give a cent in money;" that "advice is cheap," etc., etc.; but the truth is, these friendly letters of inquiry from brother bee-keepers are getting too many, not for my inclination, but for my ability to answer, so I will try to satisfactorily reply to all in this article.

My opinion is, that it is of great importance that we should all use an *uniform* section, if any, of this size; that it will pay to have some of this size on our markets; that we should try to get to the best size and shape, as soon and with as little expense as possible. Just here let me make some statements that, I think, are settled facts.

1st. Thin comb foundation, if good, is used at a profit, even at \$1.00 per pound.

2d. The thinner a card of honey is, the more surface and look of "quantity" it presents, in proportion to its weight or real amount.

3d. The thinner the comb is to be built the straighter it will be, all other influences being equal.

4th. The thinner it is the sooner the honey will be ripened, fit to seal, and the sooner sections will be *finished*, ready to come off.

These thin combs would, without the use of comb foundation, cost more in proportion to their capacity than thicker ones; but, with its use, prob-

ably less. But, again, nothing but perfectly-made foundation will be fit for combs as thin as would weigh only one-half pound, yet made in $4\frac{1}{2} \times 4\frac{1}{2}$ sections. I have some other reasons to make me fear to cut the combs down to this thinness, as was mentioned at our State convention.

5th. If the weight be reduced one-half by *thinning* the $4\frac{1}{2} \times 4\frac{1}{2}$ sections alone, they will be extremely thin, and we who use the case method will have no alterations to make, and only to order sections 9 or 10, instead of 7 to the foot.

6th. If the same reduction is made by cutting down the size of the square of the section alone, and this being done only horizontally, leaving the thickness (2 inches) the same, thus adapting the new standard one-half pound section to the present broad frames in use, fitting the present form of the tin separators, as they would, making a section $4\frac{1}{2}$ inches high by 2 thick, and say 2 wide, then this size would necessitate no changes to those who use broad frames, and while they would lose the above-named advantages of thinner combs, they would gain one, viz.: that this smaller square section would ship more safely.

Thin combs will do away with any need of separators by even the least adept and experienced, I think, and also give us richer honey. Cutting down the perpendicular width will make our space greater up and down, than horizontally, and bees prefer this shape and in it fasten their combs more securely to the section, as I found out when I used the two sizes, $4\frac{1}{2} \times 6\frac{1}{2}$ inches on its side, and 5×6 on its end.

Now, remembering that there is often "danger in extremes," I am of the opinion that a reduction in both the directions named, will be best, and that experiments will bring us to a section (without separators) about $1\frac{1}{2}$ inches thick by $4\frac{1}{2}$ high \times $2\frac{1}{2}$ inches wide, standing on end. These will not fit any of the frames or cases now most in use, without remodeling, but the truth of their appropriate shape will still remain the same.

In adopting this new standard small section we cannot afford to have more than *one* size, and we cannot afford to sacrifice the best shape the least particle, to accommodate any fixtures that any or all of us may have now on hand. I know that actual experiment, on no small scale, and by many apiarists of good judgment and no prejudices, is the best method by which to solve almost any problem in a branch of science, but theory may bring us pretty close to the true standard if we reason carefully from facts already well proven by our past experience.

We who use the new case method will have to knock our cases apart and add three more division spaces, properly spacing all, and nail together as before.

Those who use broad frames, if they still preserve that system of surplus storing (I would abandon it, I assure you, if I did), will have to cut down the width of their frames merely. 7 frames, 2 7-16 inches scant, will just fill the place of 4 frames, $4\frac{1}{2}$. Such a frame, viz.: $4\frac{1}{2} \times 2$ 7-16 $\times 1\frac{1}{2}$, used without

separators, will, I think, come as near one-half pound gross as we can get it.

I deem it a great advantage, as regards the passage of the bees, straightness of the combs, convenience of the bee-keeper in examining the cases (enabling one to see the condition of the combs better), as well as driving down the bees when removing the same, and handling the sections in and out of the cases and shipping crates, that the narrow piece be not less than $\frac{3}{4}$ narrower than the wide piece, and that this narrowness extend entirely throughout the length of both top and bottom piece of the section. We want no corners or closed tops, and all the above holds good for any section of any size.

It seems that no size of section, whether filled in company with separators or not, can be relied upon regarding any particular weight; that is, close enough to make the sale without-weight system an honest one. So let us expect our half-pound sections to be sold by weight, and not by the piece. With separators to hold the same amount of honey, the sections should be $\frac{1}{4}$ inch wider. These "separated" sections of honey have, like "yon fellow, Cassio," "a lean and hungry look," a look of much "tare," that combs born without their interference do not have.

WHO SHOULD ADOPT HALF-POUND SECTIONS FIRST?

My idea is like that of Dr. C. C. Miller's, expressed by him at our convention, that all the sizes will be more or less in demand, and he said if he knew every one but he were going to use the pound and half-pound sections he would use the two-pound, as some larger ones would be in demand. Now this is a true system of reasoning. Now, my own opinion is, that we shall find that many more one-pound sections will be demanded than two-pound; many more of one-half pound than of both the others together. There are, no doubt, a large number of beekeepers who ought, and are going to change from the two-pound section to something smaller; a larger number, who have not as yet got much of any fixtures of value. Then there are those who are yet to enter our ranks, and out of these three classes we will get enough of that size of sections to fill the demand to come, without any changes on the part of those who, like myself, have a regular all-one-size and style of surplus arrangement, all in working operation on a scale of considerable magnitude and of medium size (one-pound) sections.

For the good of those who are young in the pursuit, let me warn them not to encumber themselves with the great inconvenience of two sizes of sections, unless the demands for a total change are imperative, and the two sizes are not to be allowed to keep company longer than the entire change necessitates.

Since penning the above, I find Mr. Fornerook's circular on my desk. In it I find quoted two sizes of half-pound sections of the following dimensions, viz.: one to be used in the regular

2-inch broad frame, with separators; three tiers of five sections each in each frame, size, $3\frac{1}{2} \times 2$ 13-16 plump, x2. The adoption of this size would necessitate the changing of the separators, placing 3 narrower ones in the place of the 2 wider ones, would it not? For sections of this size square, I think Mr. F. has $\frac{1}{4}$ inch too much. I think I see great advantage in having such a size section $1\frac{1}{2}$ with separators or $1\frac{1}{2}$ without them.

The second size he proposes is $4\frac{1}{2} \times 3\frac{1}{2}$ plump, x1 $\frac{3}{8}$. This section, I fear, is too large a square, and necessitates too much thinning to get the gross weight down to one-half pound. I think the dimensions given will give us a section of about 10 to 12 ounces. I have just cut a paper model of my proposed size, viz., $4\frac{1}{2} \times 2$ 7-16x1 $\frac{1}{2}$ without separators, and it looks quite out of proportion; it is too long and narrow, yet if I knew that the bees would work as satisfactorily (to themselves and ourselves) in so narrow a space, I think I can see more advantages in this than any other form. If this should prove too narrow to suit the bees (and its narrowness is advantageous in every other respect), then I am in favor of Mr. F.'s $3\frac{1}{2} \times 2$ 13-16 in the section, only I want it $\frac{1}{2}$ inches instead of $\frac{1}{4}$ without separators," as he has it. This size will have a few minor advantages over any other mentioned, and, no doubt, suit the instincts of the bees well. I think it will weigh the plump one-half pound. I hope, in a few days, to have the opportunity of talking with one of our brightest apiarists, one who has had experience in the narrow section matter, and if he favors the one point of the narrowness, as mentioned above, I shall stand firm for the $4\frac{1}{2} \times 2$ 7-16x1 $\frac{1}{2}$, as the coming one-half pound section.

Do not confound the words, narrow and thin. By thin, we mean that which decides the thickness of the comb.

Let us hear the opinions of all who think their experience has told them something bearing upon the subject, and let your ideas of the best shape work without any bias because of any fixtures or pet theories you may have on hand.

The truth will soon come uppermost and he who gets there first will have the honor he justly deserves.

Let us settle this, in theory, at once, so that we can resettle it in practice during the season of 1883.

Eastern Indiana Convention.

The bee-keepers of Eastern Indiana met at Richmond, on the 20th of Dec., and organized an Association to be known as "The Eastern Indiana Bee-Keepers' Association." Dr. E. H. Thurston was called to the chair, and stated the object of the meeting and the advantages to bee-keepers and all interested in bees and honey, of such a bond of union. He appointed S. N. Replogle, Hagerstown; and William Kitran and E. Parker, of Richmond,

as a Committee on Constitution and By-Laws.

The officers for the year were elected as follows: President, Dr. E. H. Thurston, Hagerstown; Vice President, Dr. L. C. Johnson, Fountain City; Sec., M. G. Reynolds, Williamsburg; Treasurer, Jacob Norris, Richmond, Ind.

The Constitution and By-Laws reported by committee after some discussion were adopted. Various topics of interest were discussed, viz.: "The Best Bees," "Which is the Most Profitable Comb or Extracted Honey?" and "The Best Method of Wintering."

S. N. Replogle said he formerly wintered his bees in a cellar (built for the purpose), but now had his 72 colonies all in chaff hives; had tried both methods for three years and found that the chaff hives gave the best results. He did not think there could be anything better. He said that the $2\frac{1}{2}$ acres of sweet clover, planted six years ago, bloomed the second year, and after the third year had continued to bloom each year; the bees worked on it from morning till night; and said that he should increase the acreage and advised all to try it.

Adjourned to meet at Richmond, on Wednesday, April 1, 1883.

M. G. REYNOLDS, Sec.

Another Step in Advance.

DR. H. BESSE.

In my opinion, bee culture should, in its present advanced condition, be reduced to a science founded upon knowledge, comprehension, understanding, and a collection of the general principles and leading truths relating to apiculture.

It is expected that all advanced apiarists are prepared to do their work scientifically and in order, but this "advanced step" would stimulate and prepare young men, and those beginning the business, to qualify themselves, so that they would be prepared to readily enter into the labors of a large apiary at once. To be qualified for this they should be "graduates" in bee culture in all its branches; and in order to secure such honors they should possess the following qualifications, at least, and furnish good evidence of the same—to wit: a good character in all respects and an experience of at least one year in all the manipulations of the apiary; for all of which they should furnish certificates from some well-known apiarist, stating their qualifications and adaptability to the business.

After passing a satisfactory examination before a Board, that should be appointed by the North American Bee-Keepers' Society, they should receive a diploma, signed and sealed by the president and secretary, as well as the judges that examined the applicants. Such a diploma would be a first-class recommendation in any part of the world, and any apiarist would feel safe to employ and trust such a graduate. I repeat that none should so graduate

except those that have earned their degrees by honest toil, study and experience in the apiary, and of such qualities as to do honor to the "North American Apiarian College."

This institution should be a corporate body, to give it stability and permanence, with power to act in a judicious manner. Applicants for honors should attend the sessions of the North American Bee-Keepers' Society, and be examined during such meetings.

All graduates should pay, say \$10 or more, and be constituted life members of the society.

All present members of said society that could pass an examination and comply with the above rules, should be graduated, and then our profession would rank second to none as to respectability. Now, let us talk this matter up, through the BEE JOURNAL, and see what can be done at the next meeting of the North American Bee-Keepers' Convention. My object in writing these few scattering thoughts is to get the subject into more competent hands, and thus assist in my feeble manner to elevate to a still higher standard our beloved calling.

Prairie Farmer.

Management of Bees in Winter.

MRS. L. HARRISON.

We think it is best not to disturb bees in cold weather; provision them in fall with an abundance of stores to last until warm weather; protect them against cold, according to the climate they are in, and then let them alone; both bees and their master resting. These industrious little insects, that have toiled so faithfully all summer, should have all the good honey they want to eat.

Many bee-keepers found out to their sorrow, that it "didn't pay" to rob bees of their winter provisions, and substitute a diet of glucose. They saved their honey, but the bees were *non est*. Some advocate removing the honey from the hives in the fall, and then feed a syrup made from coffee and sugar, until they have a sufficiency for winter. This may be necessary when the honey flow is cut off by early frost, and bees work on the refuse of cider and sugar-cane mills, as this substance is not honey and sours when unsealed, breeding disease and death; but, when bees have nothing but good honey in their hives, let them enjoy it, for it is the food their Creator provides for them.

Many small after-swarms perish during winter with starvation. All such colonies have young queens, and might be the very best their owner had, the next season, if provided with food. If, through oversight or neglect, any such swarms have not been provided for, they might yet be saved, if living, by inserting alongside of the cluster, frames of honey. If this cannot be done (as all bees are not in frame hives), a food composed of honey and sugar made as follows might be given: Good sugar and honey are mixed together thoroughly until it is

thick enough to make into cakes, or roll into sticks like candy. A cake of this kind could be laid over the cluster, or a stick of candy inserted into it. In cold weather, bees might perish with plenty of it in the hive, if it was not close to them.

We know a lady who fed liquid food to bees all winter, by giving them just enough each day for their wants, and they came through all right. But such feeding as this does not pay, as it entails too much care and thought; and if they should be neglected or forgotten for a day or two, they would die, and all the food previously given, would be lost. In feeding, great care should be given, lest cold draughts are made, that would be fatal to them, and in feeding liquid food, many bees would perish in the feeders by getting chilled, if everything is not snug and warm.

The Winter Ventilation of Bees.

DR. G. L. TINKER.

In the consideration of the wintering problem there will be few to disclaim the statement that the only really troublesome factor which beekeepers now have to contend with, is the best mode of winter ventilation. To this extent then, it may be well said that the problem has been fathomed. In presenting this paper, it is with the hope that it may soon lead to a solution of the last remaining question.

No bee-keeper of experience has failed to notice the fact that bees wintered on the summer stands by the old, unprotected method, require far greater ventilation than is usually given. Few colonies survived the winter of 1880-81, that were not well ventilated; and those that came through strongest generally had free ventilation at or near the bottom of the hive, the top being sealed up as tight as the bees could make it. Several remarkable instances of wintering in box hives raised from the bottom-boards $\frac{1}{2}$ inch, or provided with very large entrances, came to my knowledge, in one of which the space allowed was nearly 50 square inches. It has been stated that colonies have been wintered in hives without bottom-boards, giving a ventilating space of over 100 square inches (see article by Mr. R. Corbett, page 215 of the BEE JOURNAL). It is my opinion that, in wintering in the unprotected hive, no upward ventilation should be allowed even through a chaff cushion.

If the inside capacity of the hive be small the entrance should be quite large, not less than 24 square inches of space, if no upward ventilation is allowed. But if the hive be very large, or if there be a large air-tight space above the bees, the entrance may be as small as $\frac{1}{2}$ inch by 10 to 12 inches, according to the strength of the colony. It does not appear that moisture collects in a large hive as it will in a small one with the same size of entrance.

It is the instinct of the bees to seal up air-tight every part of a hive but the entrance, the object being apparently to provide against the loss of heat. They are especially particular to seal up the upper parts of the hive. The conclusion is therefore unavoidable that the natural mode of ventilation is at the entrance or near the bottom of the hive. We must further conclude that if we regulate the size of the entrance to meet their necessities and give the hive proper protection, we cannot fail to have success in wintering, either in chaff hives, cellars, bee-houses, or clamps. We have the statistics, moreover, to show that the latter conclusion is not ill-founded. That the natural mode of ventilation, however, will give better results than any that the ingenuity of man can devise, remains for further experimentation to decide.

If we change the conditions in which bees are usually found in a state of nature, if we enclose a colony in a small space upon a few combs and give proper protection, we shall undoubtedly change their necessities in regard to ventilation. "Heat is life," or one of the essentials of life, which the instinct of the bees has taught them to carefully conserve. If we conserve it by the above means, or any other means, then upward ventilation becomes of possible and advantageous utility, otherwise not.

"The prime object to be obtained by any method of wintering, other things being equal, is to prevent the accumulation of dampness in the hive," according to Mr. Poppleton, whose views on this subject will stand the test of time. The natural mode of ventilation which may be depended upon to prevent an accumulation of dampness in a hive has been given. There are two other modes that have been successfully practiced, each having distinct features, but providing for upward ventilation to carry off the dampness. These modes are often greatly varied or blended into each other. Their distinctive features are as follows. We will take the old Langstroth hive for illustration. First mode: The hive is left with the bees upon all the 10 frames of comb containing from 30 to 50 lbs. of honey. The honey-board is left on with two $1\frac{1}{2}$ inch holes through it and sealed to the hive air-tight. Nothing whatever is placed in the cap which fits loosely, or it may be raised slightly by small nails at the corners. No opening in the caps, or auger holes, to permit free movement of air, is allowed, but the small crevices permit a very gradual but certain egress of the dampness from the hive. The entrance is left open the full width of the hive, or not less than $\frac{1}{2}$ inch by 10 inches. This is essentially the mode practiced by Mr. Heddon, who varies it only as follows: He leaves off the honey-board and places burlaps over the inverted honey-rack, leaving a space of $\frac{3}{4}$ inch above the frames. A case 4 inches deep is put on top and filled with chaff, planer shavings or leaves. The cover of the case is raised at the corners by small nails, and the entrance left $\frac{1}{2}$

inch by 10 inches. Only forest leaves or other loose packing over the burlap is proper by this mode, for the reason, that a colony of bees in a large space do not generate heat enough to force the dampness upwards through heavy packing. If heavy packing over the frames is desired where all of the brood combs are to be left in the hive, the ventilation could be secured by two $1\frac{1}{2}$ inch tubes to connect with the openings in the honey-board. These would permit the dampness to pass upwards into the cap as in the typical mode. A case to hold the packing would be required, in addition, the cap to be fitted over it. It will be noted that the ventilation is free as in the natural mode, but no draft of air through the hive is possible. That it is any improvement over the natural mode is very doubtful.

The second mode is as follows: Instead of leaving the bees upon 10 frames of comb they are crowded upon only 5 by division-boards, the space between the division-boards and the sides of the hive are well packed, as well as the outside of the hive. The honey-board is left off, and a few $\frac{1}{2}$ inch square pieces of wood are placed over the frames crosswise. Stout, porous cloth is laid over them and a case 10 inches deep is set on top to be filled with chaff or dry sawdust. The cap, with a 2 inch auger hole in each end, allowing a free movement of air through it, is placed over all, and the entrance left $\frac{1}{2}$ inch by the distance between the division-boards. By this mode the heat of the bees will drive the dampness out of the hive and upward through the packing most effectually. Upon passing the hand down into the packing next to the frames it will be found sensibly warm and dry all winter. That it is the heat alone that forces out the dampness it seems to me most probable. At all events, a colony of bees prepared in this manner are in a most formidable condition to withstand cold and dampness, which are the primary causes of dysentery. It is provided, in this mode, as well as the others, that the colony has plenty of young bees, plenty of stores, and winter passages through all of the combs; and also that high winds are prevented from striking the entrances of the hives by suitable means. That the latter mode above described is the best for out-door wintering admits of little doubt, but it requires more labor in preparation for winter.

The plan of "crowding the bees upon a few combs" is recommended by Mr. D. A. Jones, Mr. Poppleton, and a number of other prominent bee-keepers, the former holding that in in-door wintering it is advantageous also. I have many very interesting statistics obtained in 1881 that demonstrate the advisability of crowding a colony of bees upon a few combs in out-door wintering. But it is deemed unnecessary to give them, as the measure is well nigh self-evident, if we place any considerable packing over the bees, with the expectation to get upward ventilation.

But all this will apply only to those plans of wintering which involve a

low temperature, or a point below 50° Fahr., and a semi-dormant condition of the bees. In some northern localities, wintering by the "high pressure plan" of Mr. Ira Barber (see page 725 of the BEE JOURNAL) in which the bees are kept at a temperature not much below 70° Fahr., do their own ventilating, and eat pollen with impunity all winter, may be very desirable. Mr. Barber and his neighbors have wintered their bees for many years by the plan given, with very trifling losses. It also has the sanction of the very learned Dr. Dzierzon (see translation of Mr. Kohnke, page 153 of the BEE JOURNAL), who says: "It is my conviction that the average temperature which bees enjoy during their working season, which is from 60° to 70° Fahr., is most conducive to their well-being in winter also." While a large quantity of bees are lost by running or flying out of the hives (about 3 bushels to 100 colonies), it is likely that as many would be lost in a given time by any other method of wintering. The plan would be salutary in one respect, it would not be hampered by differences of opinion on the best mode of winter ventilation at high temperatures.

New Philadelphia, O.

For the American Bee Journal.

Eastern Michigan Convention.

The Eastern Michigan Bee-Keepers' Association met in Detroit, Michigan, Sept. 26, 1882; as the meeting was not the annual one, no business of importance was brought up, and topics for discussion were immediately brought forward. Among them were:

How large should the lower story be? Not less than 2,000 square inches.

What is the best absorbent to use in the upper stories? Sawdust, short shavings, chaff, or hay seed.

What is the best plant to grow for bee pasture, when its other qualities are considered? Alsike clover; it is a good honey plant, and makes excellent hay; it prefers a damp soil. Mr. Hunt sows 4 pounds of seed to the acre. Mr. Cottrell esteemed raspberries very highly.

What is the best plant for honey alone? Figwort first, and then motherwort. Mr. Moorhouse thought that certainty of yield should be considered.

How often should hives be examined? Several thought at least five times a season, but that surplus honey should not be allowed to accumulate.

How much food is necessary for winter? From 20 to 30 pounds.

When the construction of hives was spoken of, Mr. Higgins said he made the ends of his $1\frac{1}{2}$ inches thick; this, beside securing greater protection, was a convenience when handling the frames, as it admitted of wide rabbets.

Several other questions of minor importance, were also discussed.

A great deal of interest was taken in the meeting, and the attendance, which was larger than at any previous time, has been steadily increasing since the organization of the society.

Delegates were appointed to attend

the national convention to be held in Cincinnati.

Adjourned to meet at the call of the secretary in the spring of 1883.

A. B. WEED, Sec.

In looking over some papers I found the above Report; by an oversight I neglected to send it to the JOURNAL immediately after the meeting. I send it now, hoping that it may still be of use.

I was much interested in the article on wintering bees, by S. Corneil, which appeared lately; it contained very interesting facts, and was without the personalities which are contained in the communications of some apiarists.

I think that the enterprize of the JOURNAL is one of its most prominent characteristics.

A. B. WEED.

For the American Bee Journal.

Separators a Necessity.

J. V. CALDWELL.

The use of separators having become to me "a necessity," and as some prominent apiarists seem to think "they are a useless appendage" in the modern bee-hive, a little discussion, *pro and con*, will not be out of place, to all who have the good of the profession at heart. Now, in the first place, let me ask will it pay to use them, counting the extra cost.

That we can have fine straight combs, that can be crated and shipped without damage, and consequent loss, and yet have them built without separators, I am not ready to admit. In the BEE JOURNAL for Dec. 20, the opinion is advanced that, at least in the production of honey in one-half pound packages they will not be needed; but as the reason is not made apparent, perhaps some one will rise and explain.

It is just possible there may be certain conditions in which we may get good combs without them, but I have yet to find them. It has been said the hive must be full of bees, and honey coming in fast, then, with sections filled with good thin comb foundation, no trouble would be experienced.

Well, during the past season I determined to give this matter a fair trial, and so prepared six good colonies, with upper stories filled with wide frames, all being filled with one-pound sections, and each containing a full sheet of thin foundation; thus giving them such good facilities for comb building, that I thought, if ever good combs could be had without separators, I would have them. The result proved exactly the reverse. The honey season being a good one, the bees soon built them out and filled them with honey, but when I came to crate these same boxes for market, more than one-half had to be laid aside for the home market;—and even then, they are a "bother and vexation of spirit," as they are sure to crowd against each other and start the honey to leaking; and these combs, be they bulged ever so little, are likely to have the caps of the cells broken, if they but touch each other. It seems to me

the only advantage we could gain in discarding them, lies in the fact that more honey can be stored in the same box; but this is of little account when we sell the wood in the box at the same price as the finest honey. Supposing, then, we must use separators, shall we use wood, tin, or paper? I have never used anything but tin, though I am assured by a friend of mine, who uses wood entirely, that it is just as good as tin. However, another important item comes in here. Will as much honey be stored with, as without them? I have thought some seasons the bees were reluctant to work among them; then, again, they seemed to pay no attention, but worked as busily as though no separators were present. Let us hear from others on the subject.

Cambridge, Ill., Dec. 23, 1882.

For the American Bee Journal.

Small Sections for Honey.

F. C. BENEDICT.

By the report of the Michigan State convention, I see that the above subject was discussed, and seemed to gain favor with some of our producers. As was remarked, bee-keeping is progressive, but let us be careful not to progress in the wrong direction. The small sections meet with ready sale, in limited quantities, at fair prices, but as soon as we place them upon the market in quantities that shall reduce the price below a fancy figure, then will the producers become losers.

A prime colony of bees will produce one-third more honey in pound than half-pound sections. To obtain 1,000 pounds in half-pound packages, you must handle and make double the amount you would to get the same in one-pound packages, besides one-third more work while upon the hives. In order to obtain the same amount of money one must get one-third more in price for the half-pound sections than for pound sections, and the extra work of making and handling the smaller ones must not be taken into consideration. I speak from three years' experience with the different-sized packages, and I write this article to place the subject in its true light, so that those who are going to use the small packages may not be disappointed in the result, for I know that half-pound packages cannot be used in large quantities with profit to the producer.

While progression is our motto, we do not want to progress in a direction that shall cause our purses to get any leaner than by producing large packages, for the sake of supplying an unnecessary demand. The small package should be used as a dessert, to give our product a little more variety, when placed upon the market.

No producer can afford to use half-pound packages exclusively. I think I am safe in saying that J. C. Newman & Son, of Peoria, N. Y., were the first to place the half-pound sections upon the market in any amount, in 1879. They took well. In 1880 they used 4,000 half-pound sections, and I used the same amount; but we found we

were the losers by using so many, for we could have obtained double the amount in 2-pound sections. Newman & Son, W. S. Benedict, and myself are the only ones that have used the half-pound sections to any extent, and we would advise, from experience, to use but few, to help make a variety. When we get below one-pound packages, generally, we get below what is practical or profitable to the producer. Perry Centre, N. Y., Dec. 22, 1882.

For the American Bee Journal.

Who Are Our Best Breeders?

G. W. DEMAREE.

The article of Mr. James Heddon, on page 773, vol. 18, of the *WEEKLY BEE JOURNAL*, is calculated to excite much inquiry into the numerous methods employed to collect, select and breed up the honey bee to the highest standard of excellency.

It should not be forgotten, however, that, like the most of us, Mr. H. has adopted a theory of his own, and is therefore, not likely to look favorably upon the plans and methods of others, whose views and plans differ materially from his own.

With my imperfect mental vision, I can see, in these numerous plans, views and methods going on all over our land, the greatest possible promise of success; while, on the other hand, if all should accept the views of Mr. Heddon or Mr. Briggs, or any other breeder, the consequences would be that all would succeed or all would fail together, and, in the latter case, leaving nearly the whole field unexplored, much valuable time would be lost.

Speaking for myself, I rejoice to see the good work going forward, knowing this—that *time*, the greatest of all arbiters, must pass the final judgment.

Mr. Heddon says: "If a popular vote could now be taken as to who our best queen breeders are," etc. Perhaps I have as much faith in the intelligence of our "popular voters" as most people have, but I would not give much for a decision obtained in that way, simply because it is impossible that the popular voters could know, from their personal knowledge, the qualifications of each breeder.

Those persons who turn out hundreds of queens by means of the "lamp nursery" and weak nuclei, on the same principle that the compost heap sends forth swarms of flies, are not "breeders," they are simply multipliers of bees. To be a breeder worthy of the name he must be something of a physiologist, must know something of the laws of cause and effect. He should be well acquainted with the methods employed and followed by the master stock-breeders of the past and present. Thus equipped, he pursues his course, not without chart or compass, and if he succeeds in controlling the drones or male bees in his vicinity, he is bound to succeed in his undertaking or prove to his own satisfaction that the honey bee is an exception to all the rules of past experiences.

The modern laws of breeding point out but two great objects to be gained by following them. The one object is to breed from stock, improving the same by careful selection—the experiment being applied to one or a dozen races by the breeder if he chooses, keeping each separate from the others. The other is to breed up and establish a thorough-bred race or races, the result of combination of blood and best qualities of several races concentrated in one fixed type or race.

This is the modern idea of "thorough-bred" stock. Originally the term "thorough-bred," as applied to stock-breeding, meant no more than perfectly or thoroughly bred stock. It evidently now means more than that. It means a judicious cross of the blood of several races, bred up to a fixed type by careful selection.

I believe it is an admitted fact that no breeder has ever succeeded in establishing a fixed race by crossing the blood of just two *pure races*. Hence, Mr. Heddon's experiments, however, strongly he may insist upon the correctness of his premises, will come to grief, sooner or later.

A cross between the Italian and German races will give mongrel hybrids, without fixedness of character or uniformity of any kind, no matter how far the experiment may be carried. Those of us who remember how this class of hybrids looked twenty years ago, see them to-day just as we saw them then.

"CHIDE ME GENTLY."

A short time ago, Mr. Heddon's "dark bees" could gather greater quantities of honey where the light Italians could get none. Now, he sees only a "good season" as an explanation of Mr. Shuck's good report. Also, the secretary of the Michigan State Convention reports him as saying that the light bees are more gentle than the "dark bees" are. "Who'll be the next?"

If Mr. S. A. Shuck will look on page 1, volume 17, *AMERICAN BEE JOURNAL*, he will see that the pole and thread experiment was tried two years ago, and the actions of drones noted.

Christiansburg, Ky.

New Jersey and Eastern Convention.

The fall meeting of this society was held in New Brunswick, N. J., on Wednesday, November 1, 1882. Mr. G. W. Thompson, the President, on calling the meeting to order, delivered a stirring extemporaneous address.

Delegates were received with an address of welcome by the President, from the Philadelphia Bee-Keepers' Society, and were made honorary members. Prof. Geo. H. Cook, Ph. D., L. L. D., of Rutgers College, State Geologist and Superintendent of the New Jersey Agricultural Experimental Station, was also elected honorary member. Dr. Townsend, of Philadelphia, and Prof. Kroek of Hoboken, were appointed to fill the vacancies in the committee on question drawer.

Mr. Rue, of Manalapan, chairman of executive committee, reported a programme of exercises, first on which

was a paper on "Clamp Wintering" by C. J. Robinson, of Richford, N. Y., which was read by the secretary.

Mr. King highly disapproved of Mr. Robinson's plan. Bees, he said, needed a great deal of ventilation to carry off the carbonic acid generated in breathing; and it was his opinion that it would ruin bees to confine them in such a clamp without ventilation. A theory was started a number of years ago, that bees needed so little air, that they could be corked up tight in a bottle and live for months. He had tried the experiment, and had found, that after remaining in the bottle one night, the sides of the bottle were covered with moisture, and that the bees did not survive twenty-four hours. He thought the best way to winter bees was on their summer stands in chaff packed hives. Another consideration was, that bees in such a clamp, would not breed so as to be ready for the early harvest; while bees on their summer stands commenced to breed by the middle of March, and are strong with young bees by the time the bees from the clamps are set out.

Mr. Cook, of Caldwell, thought that bees might be wintered successfully in this way, but they would suffer from spring dwindling when set out, as from any kind of in-door wintering. Besides the plan was too expensive.

Mr. Rue thought the plan might do well enough in cold localities, but that it was entirely unnecessary in New Jersey, as bees wintered well here on their summer stands.

The Secretary thought that the subject of wintering was yet the most important that bee-keepers could discuss. He had wintered his bees always out of doors, far north, in New York State, and also in New Jersey, and while, with plenty of honey, he could keep every colony alive, yet from the opportunities he had had of studying bees wintered inside, he had concluded not to winter longer out of doors. At every warm spell, in the middle of the day, the bees out of doors leave the cluster and go to the outside of the hive to carry honey into the middle of the cluster. It soon grows cold enough to chill a great many so that they do not return. Thus the strength of the hive is decimated worse in New Jersey than in higher latitudes. Mr. Robinson's plan seemed the most practical way of protecting bees in winter. Many persons in this age are greatly troubled by carbonic acid, more in imagination than in reality. He thought the bees could stand all the carbonic acid generated all winter in their semi-torpid state. It was idle to talk of the bees being ruined in this plan of wintering, as it has been practiced for years by Mr. Robinson; and he reports that he can winter successfully very small colonies and that he has never lost a single colony in the clamps. Mr. Hutchinson, a prominent bee-keeper of the West, had tried the plan last winter, under Mr. Robinson's direction, with a part of his stock, and had not ruined his bees; but was so well pleased, as he reported to *Gleanings*, that he expects to winter largely in this way the coming winter.

Mr. King said he learned from neighbors of Mr. Robinson, that his theories of wintering bees were better than his practice.

Prof. Kroeh thought that it would do no good to theorize as to whether bees would winter in this way; no theory could stand against a fact, and as bees have been wintered in that way, that settled that it could be done, and now it remained for us to explain how they were able to live, without the air seemingly necessary to support life. He would suggest that Mr. Robinson did not exclude the ventilation as effectually as he thought. Quite probably the air penetrated the covering.

Dr. Townsend said, that as a physiologist, he believed that a constant supply of fresh air was necessary to the support of life, and he thought that air undoubtedly penetrated the covering.

The President said that he too believed that air came through the covering. Air would get through lately moved earth for a great distance. A neighbor of his had been building a silo, and had made one side of it by a bank, six feet thick, of ground dug out of the pit. He believed air would penetrate the bank, enough to spoil the fodder.

Next on the programme, was a paper by Prof. Cook of the Michigan Agricultural College, on a "Plan for Gathering Bee Statistics."

Mr. King said that accurate statistics of the honey product had never been gathered.

Mr. Poole inquired why they could not get all the statistics required from the census reports?

Mr. King answered that those reports were worthless, as far as bees and honey were concerned. Mr. Landreth, when at the head of the Agricultural Bureau, had told him that, although the census reported a honey crop of 15,000,000 lbs., he had data in his possession showing a yield of at least 35,000,000 lbs.

On motion of Mr. Cook, the association adopted the plan of Prof. Cook, and Mr. Rue was appointed a committee of one to put himself into communication with the National Association for the purpose of endeavoring to carry out this plan.

The next paper on the programme was by the Secretary, on "Too many Eggs in One Basket."

Mr. Cook said in one light the paper was right; but in another it was wrong. Men to succeed in anything, must focalize their energies, and learn one business well, and do that in a proper manner.

Mr. King said that the Secretary was unfortunate in keeping his bees in a poor location, or from practicing too closely Mr. Robinson's theories, or from too much carbonic acid, and hence spoke in a discouraging manner. He said he could name multitudes of specialists who had made a great deal of money in bee-keeping—among whom were G. M. Doolittle, Harbison, and Jas. Heddon. He said bee-keepers were a good deal like miners standing around a hole, who, when others were around, acted as if there was nothing in it, but when they got a

chance, just raked out the gold dust. Mr. Betsinger had told him that he had made an average of 100 pounds from every colony ever since he had been in the business.

Mr. Poole said he had been enticed into the bee business, by supply dealers, especially by the President, Mr. King, and the Secretary. He had taken a great deal of honey the last season, but yet he agreed with the paper, that the bee business, like the poultry business, was not adapted to be carried on on a large scale. He did not value it for the money there was in it, but for the pleasure it afforded him and for the valuable lessons he could get from it.

The report of the committee on question drawer was next in order.

The first question—"Can Virgin Queens be Introduced Successfully?"—was answered by Prof. Kroeh. Yes; by putting them into the hive when less than one hour old, without a cage.

Mr. King could introduce a virgin queen several days old, by spraying her and the bees with peppermint water and making them all crawl some distance to the hive.

The question—"How can Nuclei be United for Wintering?"—was answered by Mr. King. He said that he took frames from at least three nuclei and set them close to the hive he wished to use. Then he put them quickly into the hive and closed it. The bees from so many hives were too much confused to quarrel or injure the queen.

The question—"Are Winter Passages Through the Combs Necessary?"—was answered by Dr. Townsend in the negative. He said that the holes mutilated the combs too much—that the same end could be attained by small sticks laid across the tops of the frames.

Mr. King said he stretched canvas on sticks, so as to have an open space above the frames. On this he placed the cushion.

Prof. Kroeh said he used to put sticks over the tops of the frames, bent in the form of a bow, by putting the ends against the sides of the hives, thus making an open space above the combs, where the bees could cluster; but upon reflecting that there was no honey for the bees in this space, where they were made to cluster by the warm air all ascending there, he had abandoned the plan.

Mr. Cook said that in visiting Capt. Hetherington's apiary he had seen little coils of tin, permanently fastened near the middle of each comb, for winter passages.

Mr. Poole said that he put a frame, covered with wire cloth, over each of his hives, so that he could lift up the cushion and see what the bees were doing, without their being able to see too much of him. He considered this an excellent plan, although the worthy President had told him that he would not have the things on his place. On examining his bees in winter, he observed a constant current of bees over the tops of the combs. He kept a couple of colonies in a bay window, in a parlor. The heat in the parlor in winter did not go above 45° and the

bees were quiet and did not fly out when the weather was unfavorable.

The next question—"How Long will a Queen Remain Profitably Prolific?"—led to a lengthy discussion on a theory of Ulivi, that queens are fertilized inside the hive and frequently. Prof. Kroeh, although undecided as to the truth of the theory, gave an account of some of Ulivi's observations and defended his conclusion.

Mr. King said that the theory could not be correct, as they sent Italian queens to Dakota, New Zealand and other places where Italian queens had never before been sent. They were put into hives of black bees and continued to produce pure Italian bees, when there could have been nothing but black drones, if any, in the hives, for a long time.

The Secretary pronounced Abbe Ulivi a "crank." His theory was against the most ordinary facts constantly observed by every bee-keeper. Nothing was more common than to see a queen from a black colony filled up with black drones becoming fertile by an Italian drone from a neighboring apiary, and the opposite. This cannot be explained on the theory of Ulivi. Every bee-keeper has seen his young queen fly off unincumbered and return in a short time with something attached, which Ulivi says is excreta. If all his pretended microscopical investigations are of the same kind as this, they are obviously worthless, as any one can see with the naked eye that they are the copulative organs of the drone.

He had examined them carefully under the microscope and always found the appendage to be torn parts of the drone. He and several other persons had seen this copulation take place before their eyes, and always saw a lacerated and dead drone as the result. He had, in conducting some experiments, kept six young queens shut up in nuclei, well supplied with drones, till after they had been laying several weeks, when it was found, in every case, that they apparently had not been fertilized in the hive, as all the eggs they laid produced drones.

Prof. Kroeh said that to show what chance there was for loop-holes in observations, he would say, that Ulivi had found with his microscope that the vagina of the queen was entirely too small to be entered by the organs of the drone.

Several members were on their feet to explain how the copulation was effected, but as many members had to take the train then nearly due, a motion to adjourn prevailed, New York city being selected as the place for holding the spring meeting.—*Bee-Keepers' Exchange.*

☞ The time for the usual winter rush of correspondence is here, and we wish to impress upon all our patrons the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

SELECTIONS FROM OUR LETTER BOX

Well Pleased with Progress Made.

The BEE JOURNAL is full of interest. I have been pleased by the progress made by bee-keepers in apiculture and hope that this science will eventually be fully developed. I had 2 colonies of bees last spring, one of which swarmed twice; the second swarm escaped while being hived. From the first swarm and parent colony I took about \$18 worth of honey in 2-pound boxes. The other stored none and did not swarm. The 3 colonies are packed with timothy chaff, on their summer stands, with plenty of bees and plenty of honey for winter.

WM. A. BRUNDAGE.

Lodi, N. Y., Dec. 22, 1882.

Do Bees Hear?

On page 803, of the BEE JOURNAL for Dec., 1882, reference is made to certain remarks of Sir John Lubbock, and the influencing of bees, when swarming, to settle by making loud noises, etc., etc. I am decidedly of the opinion that it is not to the sense of hearing on the part of the bees, that the custom of beating tin cans, etc., took its rise, but to the sense of hearing in the human family, and why? For the simple reason that the ancient laws relating to bees, vested the ownership in a swarm only to him from whose grounds they departed, provided he followed them, and kept them in sight until they alighted. Now, what more natural than to "kick up a row" for the sole purpose of letting others know that the bees seen in flight were being followed. I regret that I cannot at present consult my library of bee books and give the words of the ancient laws. I think the wording would go far to prove my hypothesis correct.

ARTHUR TODD.

Philadelphia, Pa., Dec. 25, 1882.

Brood Killed by Overheating, etc.

Owing to changing my location and moving my bees, last spring, my success has not been as great as it otherwise would have been. I sold a part of my bees; moved 21 colonies; lost 1; bought 20; increased to 67; obtained about 1,600 lbs. of comb honey, and 400 lbs. of extracted honey. I might have extracted from 600 to 800 lbs. more, but was called away on other business at the proper time for extracting it. The most of my swarms came out late but gathered an abundant supply of honey to winter on, and many of them some surplus. One swarm came off the 20th of Aug.; on the 25th of Sept. I took 23 lbs. of comb and 24 lbs. of extracted honey and left six nice frames for them to winter on. I thought that doing well, but when I read in the BEE JOURNAL of colonies giving from 400 to 600 lbs. each, of surplus (which, by the way, looks a little "fishy"), I feel like having nothing to say. Would it not be well to

have the *modus operandi* by which such yields are obtained? Or would there be danger of glutting the market? You will perhaps recollect, Mr. Editor, that I wrote you in July last, asking your opinion and advice in regard to what I feared was foul brood, but which proved, as you surmised it would, to be "parboiled or overheated brood," caused by not giving proper ventilation in moving. If agreeable, I will, at another time give you my experience in getting rid of the dead brood and building up the colonies, which I succeeded in doing very successfully. I do not want to miss a single number of the BEE JOURNAL; it is indispensable.

REUBEN HAVENS.

Onarga, Ill., Dec. 26, 1882.

My Report.

I commenced the spring with 5 good colonies and one that was queenless; increased to 25, by natural swarming; all in good condition. I obtained 1,032 pounds of comb honey.

L. FATZINGER.

Janesville, Wis., Dec. 20, 1882.

Wintered without Loss in the Cellar.

In December, 1881, I put 29 colonies in my cellar, and did not disturb them till spring. They came out "with flying colors" on the 15th of the following April, all in good condition, without the loss of a colony or a queen. I sold 15 colonies at \$10 each, which left me 14 to commence the season's work. By natural and artificial swarming they increased to 60 colonies during the season. I also realized about 3,000 lbs. honey, being about equal parts of extracted and in the comb. We had an abundant flow of honey for about six weeks. Bee-keepers are greatly encouraged in these parts. Long life to the Weekly BEE JOURNAL. I would not do without it for ten times its cost.

G. W. STARK.

Holmesville, Neb., Dec. 25, 1882.

Packed on Summer Stands.

My season's work with the bees has been satisfactory. I started with 55 colonies on June 7, 1882; increased to 250 colonies; had 3,500 lbs. of comb honey and 500 lbs. of extracted; total 4,000 lbs. I have sold about one-half up to date, at an average of 17 cents per lb. My bees are all packed in leaves, on their summer stands, and look comfortable.

H. S. HACKMAN.

Peru, Ill., Dec. 21, 1882.

Sections too Small.

Our bees seem to be wintering nicely so far; the winter has been favorable, up to the present time; we have had but little cold weather; the mercury was down to 10 below zero, on the morning of Dec. 7th, but the cold wave was of short duration. I have just read the article on the size for the half-pound sections, or "The Section for the Future." I give it as my opinion that the size of the section will have to be reduced, making allowance for the comb to be the usual or nearly the usual thickness. I think it will be

found impracticable to retain the usual sized section and force the bees to build *thin* combs. However, I think if it is done, that separators will have to be used; if sections are put on the required thickness. Allowing the combs to be $\frac{3}{4}$ of an inch thick, supplied with foundation (without separator) it will be found that some of the combs will be about the usual thickness, while others will be very thin; perhaps only drawn out on one side. I merely give it as my opinion that when the object sought is accomplished separators will be used, allowing just the space required, and I fear that bees will be slow to commence work in such small spaces.

L. G. PURVIS.

Weston, Mo., Dec. 22, 1882.

My Season's Work for 1882.

I commenced in the last spring with 30 colonies; 25 fair and 5 weak ones, (Italians and hybrids). I have increased 100 per cent.; taken 110 lbs. of extracted and 20 lbs. of comb honey, per colony, spring count. I am selling the honey, in the home market, for \$1.25 for 10 lb. tin pails, and 65c. for 5 lb. tin pails. We had honey dew for about six weeks, mostly on hickory leaves, which seemed to be dripping wet with the dew. The leaves finally died, apparently from the effects of the dew. The bees visited the dew quite lively, early in the morning. We had but one light rain during the honey dew flow.

A. S. EDSO.

Martinsville, Mo., Dec. 20, 1882.

A Good Showing.

This is my statement of what I have done, the present year, with the aid of the JOURNAL: I took from 14 colonies, 2,400 lbs. of honey, in one and two-pound sections. My best colony gathered 400 pounds, in one-pound sections, and 150 pounds in frames, $9\frac{1}{8} \times 17\frac{5}{8}$ inches. From four of my best I took 1,930 pounds in one-pound sections. I use the Parker chaff hive, improved by myself, which I think is the best hive in use for winter or summer. I have in winter quarters 36 colonies in good condition. I have sold all of my surplus honey for 20 and 22 cents per pound.

W. H. WILL.

Bloomington, Ill., Dec. 26, 1882.

Report for 1882.

I put into winter quarters 16 colonies in Hiram Roop's winter-protector and lost 3 light colonies. I commenced the spring of 1882 with 13 colonies and increased to 30. My crop of honey is 1,250 pounds of comb honey in 2-pound sections, and 555 pounds of extracted. The bees are in splendid condition for winter, except two light colonies.

I. J. LUCAS.

Staunton, Mich., Dec. 26, 1882.

In a Snow Drift.

I dug 7 colonies of bees out of a four-foot snow drift, under which they have been for three or four weeks. They were all lively, and had a little fly, but they did not fly far.

C. W. YOUNG.

Stratford, Ont., Dec. 22, 1882.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES for 1883.

20 cents per line of space, each insertion,

For either the Weekly or Monthly Editions.

A line of this type will contain about 8 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

SPECIAL RATES.—Advertisements will be inserted in both Weekly and Monthly editions, at the following prices, if wholly paid in advance:

SPACE.	One month	Two months	Three months	Six months	One Year.
1 in. 12 lines	10.00	18.00	25.00	38.00	50.00
2 in. 24 lines	20.00	32.00	40.00	60.00	80.00
3 in. 36 lines	25.00	40.00	50.00	75.00	100.00
4 in. 48 lines	32.00	50.00	65.00	90.00	125.00
5 in. 60 lines	40.00	60.00	75.00	110.00	150.00
6 in. 72 lines	45.00	70.00	90.00	130.00	175.00

For the Weekly alone, 20 per cent. less than the above rates. On yearly advertisements, payments may be made quarterly, but must be in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Articles for publication must be written on a separate piece of paper from items of business.

CLUBBING LIST.

We supply the **American Bee Journal** and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club
The Weekly Bee Journal.....	\$2 00..	
and Gleanings in Bee-Culture (A. L. Root) 3 00..	2 75	
Bee-Keepers' Magazine (A. J. King) 3 25..	3 00	
Bee-Keepers' Exchange (Honk & Peet) 3 00..	2 75	
Bee-Keepers' Guide (A. G. Hull).....	2 50..	2 35
Kansas Bee-Keeper.....	2 60..	2 40
The 6 above-named papers.....	6 35..	5 50
The Weekly Bee Journal one year and		
Prof. Cook's Manual (bound in cloth) 3 25..	3 00	
Bees and Honey, (T. G. Newman) " 2 75..	2 50	
Binder for Weekly Bee Journal.....	2 75..	2 50
Apiary Register for 100 colonies.....	3 50..	3 00
Apiary Register for 200 colonies.....	4 00..	3 50

The **Monthly Bee Journal** and any of the above, \$1 less than the figures in the last column.

Sample Copies of the **AMERICAN BEE JOURNAL** will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the **BEE JOURNAL**.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

The **BEE JOURNAL** is mailed at the Chicago post office every Tuesday, and any irregularity in its arrival is due to the postal employees, or some cause beyond our control.

Attention is called to a few changes in our clubbing list for 1883, as given on this page. Those interested will please take notice.

We carefully mail the **BEE JOURNAL** to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Do not let your numbers of the **BEE JOURNAL** for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Advertisements intended for the **BEE JOURNAL** must reach this office by Saturday of the previous week.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

It Pays.—I have sold all of my sweet clover seed. Advertisements in the **AMERICAN BEE JOURNAL** pay.

J. R. GOOD.

Nappanee, Ind., Dec. 24, 1882.

Attention is called to our *new* and liberal advertising rates for 1883.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50. The Monthly BEE JOURNAL and either of the above for one dollar less.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure
and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is
"fully up with the times" in all the various im-
provements and inventions in this rapidly devel-
oping pursuit, and presents the apiarist with
everything that can aid in the successful manage-
ment of the honey bee, and at the same time pro-
duce the most honey in its best and most attrac-
tive condition. Chief among the new chapters are
"Bee Pasturage a Necessity," "Management of
Bees and Honey at Fairs," "Marketing Honey,"
etc. Price, bound in cloth, 75 cents; in paper
covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this ex-
cellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many
times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to
bee raisers.—Indianian, Chato, Ind.

A neat and abundantly illustrated hand-book of
apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109
beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap
form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make
bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of
every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the
care and management of bees.—Democrat, Alle-
gan, Mich.

The most perfect work for the price ever yet pro-
duced on the subject of bee-culture.—Anti-Monop-
olist, Lebanon, Mo.

The engravings are fine. It is gotten up in the
very best style, and is cheap at the price.—Farmer,
Cleveland, O.

It comprises all that is necessary for successful
bee-culture, save experience and good judgment.
—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries
in the management of these little workers.—Plain
Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who
contemplates keeping bees can do without.—Farm-
ers' Journal, Louisville, Ky.

Gives minute details for the management and
manipulations necessary to make bee-keeping a
success.—Col. Valley and Farm.

It embraces every subject that can interest the
beginner in bee-culture. The engravings perfectly
illustrate the text.—Farm and Fireside, Spring-
field, O.

Embraces every subject of interest in the apiary,
giving very thorough details of the management
and manipulations necessary to make bee-keeping
a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner,
and contains valuable information for all readers,
even though they be not directly interested in the
care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains
a complete resume of the natural history of the
little busy bee, as well as of all that one needs to
know in their care and management.—Chicago
Herald.

Describes all the newest discoveries in the art,
by which the production of delicious and health-
giving honey is obtained, as well as how to prepare
it for the market in the most attractive shape.—
Signal, Napoleon, O.

Contains a vast fund of information in regard to
bee-culture. He who would keep abreast of the
times must keep posted in all the improvements in
his line. We advise all interested to get a copy of
this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the
beginner. It describes all the newest discoveries
in the art by which the production of delicious and
health-giving honey is obtained, as well as how to
prepare it for the market in the most attractive
form. It is embellished with beautiful engravings,
and is the most perfect work of the kind, for the
price, that has ever come under our notice.—Far-
mer, Lancaster, Pa.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,**By A. J. COOK,***Of Lansing, Professor of Entomology in the**State Agricultural College of Michigan.***320 Pages; 133 Fine Illustrations.**

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is truly "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*.

It appears to have out the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST*.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*.

This book is just what everyone interested in bees ought to have, and which, no one who doubts it, will ever regret having purchased.—*Much. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is truly up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, M. D*

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABEE DU BOIS*, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *valde precium* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00 by mail prepaid. Published by

THOMAS G. NEWMAN,

West Madison Street, CHICAGO, ILL.

BOOKS,

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apibry.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping. by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject. —\$1.50.

Novice's ABC of Bee-Culture. by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book. by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey. or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur. by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory—presents the fundamental principles of bee-culture, and formulates the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine. by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market. including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Foul Brood: its origin, development and cure. By Albert R. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing. A 24-page pamphlet, by Ch. & C. P. Dudant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity. by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Moth: 24 pages. It gives Mr. Moth's views on the management of bees. Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. Price 5 cents.

Bees in Winter. with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. Price 5c.

Queen-Rearing. by Henry Alley.—A full and detailed account of "TWENTY-THREE years' experience in rearing queen bees." The cheapest, easiest and best way to raise queens. Never before published. Price \$1.00.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 300 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and plank by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 55 c. postpaid.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

More's Universal Assistant, and Complete Mechanic. contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. MENDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood case elegantly finished, 3 strings, 7 1-3 Octaves, full patent cantante scales, our new patent overstrung scale, beautiful curved legs and lyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

Our price for this instrument, boxed and delivered on board cars at New York, with one Piano Cover, Stool, and Book, only.....\$245.

Reduced from our late wholesale factory price, \$295, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Pianos, \$160 up. Over 15,000 in use, and no one dissatisfied. Purchaser's Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years.

SHEET MUSIC 15c price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

MENDELSSOHN PIANO CO.,
215 mlv Box 2958, New York.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small **White Shark**, caught in the Yellow Sea, known as *Carcharodon Rondellii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE. A THE WHITE SHARK OIL PERSONALLY TESTED, NOT FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

A Honey Feast.—A new and novel way of developing a taste for honey, has been introduced by Mr. Eugene Secor, of Forest City, Iowa. It is worth being adopted in every locality, and would help wonderfully to advertise the honey-producer of any locality. To popularize its consumption should be the aim and object of every producer, and Mr. Secor has found a very neat way of advertising that will pay him well. From the *Winnebago Review* we extract the following notice of it:

The ladies of the Methodist church furnished something new in the way of an entertainment during the first evening of their fair last week. Eugene Secor, the king bee-man of this locality, offered to them all the honey they could use for one evening, and on the strength of that offer they advertised a Honey Feast. The bill of fare included choice comb honey, extracted honey, both liquid and candied, milk and honey and honey cake, the latter furnished by Mrs. Secor. Hot biscuit were served. The crowd "got away" with a goodly amount of sweets, but we did not hear of anyone being made sick by it, and we are assured that the supply was not exhausted, and that the ladies cleared a nice little sum by the arrangement.

The Cause of Success.—Our readers are well aware that Mr. E. C. Jordan is one of the most successful honey-producers in Virginia. We are in receipt of a copy of the *Times*, of Winchester, Va., in which we find the following notice:

Mr. E. C. Jordan, of Jordan's White Sulphur Springs, laid on our table, the other day, some copies of the *AMERICAN BEE JOURNAL*, published in Chicago. It treats fully of everything connected with the production of honey and management of bees, and we should think would be invaluable to those engaged in this pleasant and profitable business. Whether Mr. Jordan has profited by its suggestions or not we are unable to say, but we do know that he is a most successful bee-man and the products of his apiary are not surpassed by any other in the country. His "bee orchard" is a source of no small profit, and his honey is always in demand in the city markets, at the highest price.

The *Winchester News* remarks that Mr. Jordan has been exceedingly successful with his bees, and has shipped large quantities of honey to the large cities in the South, and that it commands large prices, and is eagerly sought after. This shows what energy and improved methods can do, in the development of the markets for honey.

We notice that the Rev. O. Clute, of Iowa City, is to give a lecture on "Bee-Keeping by Modern Methods," on Thursday, Jan. 11, before the Iowa State Agricultural Society and Farmers' Alliance, at Des Moines, Iowa. Mr. Clute is an eloquent speaker, as well as an enthusiastic bee-keeper, and it will no doubt be a very interesting lecture.

The eldest son of Dr. N. P. Allen, ex-president of the North American Bee-Keepers' Society, died of typhoid fever, Nov. 29, 1882.

The Small Sections for Honey.

This appears to be the all-absorbing topic of the hour. Several articles appear in this number on the subject, which is being thoroughly discussed on all sides and in all its phases.

Mr. James Heddon, of Dowagiac, Mich., has sent us a nice sample of his new half-pound, dovetailed, white-wood section, described on page 27. It is very handsome in appearance, and, we think, of the right shape: $4\frac{1}{4}$ inches high, $2\frac{1}{2}$ to $2\frac{3}{4}$ inches wide, $1\frac{1}{2}$ inches thick. Mr. Heddon advises caution in changing to small sections, and says: "You may be sorry if you do it."

Dr. G. L. Tinker, New Philadelphia, O., also sends us one, $3\frac{3}{4}$ inches square and $1\frac{3}{8}$ inches thick. When filled with honey, the one sent by Dr. Tinker will look the most for the money, but, we fear, the extra capping and comb foundation will make it too expensive to be profitable.

Mr. L. H. Scudder, New Boston, Ill., gives some very strong arguments against decreasing the size of the package, and Dr. C. C. Miller, of Marengo, Ill., inclines to that side of the question. The Doctor very sagely remarks, that if many are going to adopt the half-pound size, the present marked difference in price may not continue.

Messrs. J. C. Newman & Son, Peoria, N. Y., who claim to be the originators of the half-pound sections of honey, describe the difficulties to be surmounted in their first use, and advise caution. They also say that separators are absolutely essential, and that straight combs cannot be produced so as to crate nicely without separators, and find that those made of thin wood are the best.

Dr. E. B. Southwick, Mendon, Mich., makes the following criticism on the size of the small sections. But, whew! He has gone down another notch—to quarter-pounds—*reductio ad absurdum*—perhaps. He says: "Mr. Bingham has given $9\frac{3}{4}$ cubic inches as the size of one-half pound of honey. That, I think, is correct in extracted, but not in comb. His shaving-down experiment shows that it takes $11\frac{1}{4}$ cubic inches to make one-half pound, and when we measure the inside of a one-pound section we find it contains about $26\frac{1}{4}$ cubic inches, thus allowing $3\frac{3}{4}$ cubic inches for extra, and I think it is needed. As my hive is so arranged that I can use any size of sec-

tions, I think, next year, I will try a few $3\frac{1}{2} \times 3\frac{1}{2} \times 1\frac{1}{2}$, upper side, for one-half pound; and a few $3 \times 3 \times 1\frac{1}{4}$, upper side, for one-quarter pound. The further we run an absurdity, the sooner we find we are wrong. There is always so much waste room between the comb and sections that I think these sizes none too large."

The BEE JOURNAL would strongly advise caution. Let it be thoroughly discussed, and, then, let a few be tried and, if they will increase the consumption at good-paying prices to the producer, then increase the dose, another year; but do not attempt to glut the market, else it may have the opposite effect.

All sizes will be needed to stock the market, and if the "ten-cent" packages of honey should revolutionize the market, causing ten times the amount to be used, no one could or would complain. Any move that would increase the demand for honey, is in the interest of the producer, and will redound to his advantage.

The Strength of Bees.—The *Norristown Herald* makes the following comparison between the strength of bees and horses:

Mons. Pateau has discovered that while a horse can pull only six-sevenths of its weight, a bee can pull twenty times its weight. When some one discovers how to grow bees as large as horses, the latter will have to take a back seat. But it would be fatal to fool around the heels of such a bee. With its javelin it could pin a man against the side of the stable. Perhaps it would be better not to raise bees any larger than the present crop.

✂ We regret to learn that Mr. L. H. Scudder, of New Boston, Ill., has been severely injured. He attended the convention at Chicago, last October, and helped to make that meeting very interesting. A few days after that, he returned home, and now writes us as follows: "A few days after reaching home I had the misfortune to have a team run away with me, by which I was so much injured that I have been unable to perform any labor. My right arm was dislocated at the shoulder, besides being badly bruised. My head also received several severe cuts and bruises from the horses' feet. However, I am so far recovered that I feel that I must be doing something." We extend our sympathies to friend Scudder, and hope he will soon *entirely* recover from his injuries.

Mr. Heddon as a Specialist.

The Dowagiac *Republican* in a recent issue, gives a long notice of the apiary of Mr. Heddon, and its growth, year after year. From it we extract the following:

One of the most important business interests in this city is Heddon's apiary and bee-keepers' supply manufactory. The proprietor, Mr. James Heddon, begun bee-keeping as a specialty in 1869 and was the first specialist in Michigan, there being but few in this country at that time. His capital stock did not exceed \$500, but the business has increased steadily since, giving him a nice profit, which Mr. Heddon has, for the most part, kept in the business. He has owned at one time as many as three apiaries and 550 colonies of bees, having now 400 colonies in his apiary in this city. He has always produced both comb and extracted honey, formerly giving preference to the latter, but of late years producing mostly comb.

The largest yield of honey from one hive, was 410 lbs., during one season. The largest yield from one hive in one day was $29\frac{1}{4}$ lbs. This was extracted honey, except about 50 pounds of the 410. These figures only show what can be done, with all conditions the most favorable. With so many bees as he now keeps together, in one area (an area, or bee range, consists of a field whose diameter is 6 to 8 miles), the *pro rata* yield is quite small. Where nothing was gathered before, he has gathered together and sold something over \$20,000 worth of this produce during the last 13 years.

Mr. Heddon has formerly given employment to one or two hands, during 8 months of the year, and now he employs three and four during the summer season, and one all the year around.

This year's crop of honey was some over half comb, the bulk of which was sold to Colter & Co., of Cincinnati, they sending \$720 for 4,000 pounds, the price being 18 cts. per lb. here, cash in advance. He still has some 3,000 pounds of extracted honey now on hand (candied solid) which he is keeping to fill orders for regular customers, who depend upon him from year to year, and the home trade.

✂ The time for the usual winter rush of correspondence is here, and we wish to impress upon all our patrons the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

✂ We are sorry to learn that Mr. Paul L. Viallon has lost his little boy—the pet of the household.

✂ Attention is called to our *new* and liberal advertising rates for 1883.

Habits of Bees in the South.

A correspondent of the Washington *Gazette*, who has a very imaginative and fertile brain, tries to explain and account for a foolish story that has been again and again published in the papers all over the country, about bees losing their inclination to store honey, when they are placed in the South where they experience but little of winter. The story, so often told, is as foolish as it is untrue, and the *Gazette* correspondent will try in vain to account for that which is itself untrue, as well as unreasonable. The intelligent bee-keepers will be amused and at the same time disgusted, at the following, which is received as truth by thousands of persons who know nothing more about bees, than that they use their sting as a means of defense, and that the honey they store up is delicious. The item referred to is as follows:

THE RECKLESS BEE.—An experimenter in Southern agriculture told me the following history of Northern bees in the South. He took a colony of the little gratuitous honey-makers down to Florida. The first year they reveled, thrived, and stored honey nearly all the unvaried summer time. But the second year a few of the more reflective bees evidently turned the thing over in their minds thus: "This country has no winter to provide against; what is the use of laying up honey when the flowers blossom all the year round?" These bees exerted enough influence among their friends to keep a good many bees from laying by any sweet merchandise the second year of their exile.

But the prudential instinct so strong in the little insect, prevailed with the majority. They evidently said to themselves: "Perhaps this has been an exceptional year. Next season may bring cold and snow and dearth of flowers." So there was quite a stock of honey laid by on the second year, in spite of a few strikers. But by the third year the conviction had evidently thoroughly penetrated the bee mind that it was foolish to lay up in a land of eternal blossom. They made just enough to last from day to day, abandoned themselves to living from hand to mouth as recklessly as does any tropic-born butterfly.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Local Convention Directory.

1883.	Time and Place of Meeting.
Jan. 9-11, Northeastern, at Syracuse, N. Y.	G. W. House, Fayetteville, N. Y.
10, 11.—Indiana State, at Indianapolis.	Dr. J. H. O'Rear, Pres.
11, Nebraska State, at Wahoo, Neb.	Geo. M. Hawley, Sec.
16.—N. W. Ill. and S. W. Wis. at Freeport.	J. Stewart, Sec.

May 11.—Iowa Central, at Winterset.	J. E. Pryor, Sec.
—, —Texas State Convention, at McKinney.	Dr. W. R. Howard, Sec.
Oct. 17, 18.—Northwestern, at Chicago, Ill.	Thomas G. Newman, Sec.
9, 10.—Northern Mich. at Sheridan, Mich.	O. E. Goodno, Sec., Carson City, Mich.
Dec. 5-6, Michigan State, at Flint.	H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Convention Notices.

The Northeastern Bee-Keepers' Association will hold their thirteenth Annual Convention in the City Hall, at Syracuse, N. Y., on the 9th, 10th and 11th days of January, 1883.

Business of great value to every bee-keeper in the State will be brought before the meeting. Every member is requested to attend and bring their friends, that all may be benefited by the action there taken.

The question drawer will be opened each day, and questions answered and discussed. All are invited to send questions. Appropriate diplomas will be awarded to successful exhibitors of implements, etc. Let all attend.

GEO. W. HOUSE, Sec.

The annual meeting of the Champlain Valley Bee-Keepers' Association will be held at Middleburg, Vt., on Thursday, January 18, 1883, at 10 a. m.

T. BROOKINS, Sec.

The Nebraska State Bee-Keepers' Association, will hold its annual session in Wahoo, Saunders county, Neb., commencing Thursday, Jan. 11th, 1883. Arrangements have been made with the railroads to secure 12 fare for the round trip. The Saunders county Bee-Keepers' Association will furnish entertainment free to all visiting apiarists. Bee-keepers from neighboring States will be welcomed.

T. L. VONDORN, Pres.

GEO. M. HAWLEY, Sec.

The Southeastern Michigan Bee-Keepers' Association will hold their annual meeting in the courthouse at Ann Arbor, Jan. 20, 1883. All are invited.

H. D. CUTTING, Pres.
G. J. PEASE, Sec., Ann Arbor.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

The following committees have been appointed, and the programme arranged for the next meeting, by the executive committee; viz: on Resolutions; Apiarian Supplies and Exhibits; Subjects for Discussion; and Arrangements, to receive and entertain those in attendance from abroad.

Programme.—President's Address. Subject—State and National Conventions.

Subjects for general discussion:

Essays.—The "Coming Bee," W. H. Andrews. Honey plants, Native Horsemints, different varieties, Wm. R. Howard. "Extracted vs. Comb Honey," W. K. Marshall, D. D. "Bee-Moth," W. H. Andrews. "The Queen Bee, her nature and habits, Wm. R. Howard. "The different races of bees in America; their relative value to apiculture," W. K. Marshall, D. D.

Other essays are promised, and a general good time is anticipated. Ample arrangements are made to accommodate those from a distance. Those wishing to place anything on exhibition or correspond with the committee of arrangements, will be promptly attended to, by addressing, W. H. Andrews, President, McKinney, Collin Co. Texas. All other correspondence to the Secretary. We would be pleased to have any one propound questions of interest for discussion, as we have found great interest, as well as valuable information gained by the discussion of questions contributed to our "Question Box."

WM. R. HOWARD, Sec.

Kingston, Texas.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883.

C. T. LEONARD, Sec.

The annual meeting of the Mahoning Valley Bee-Keepers' Association will be held at Berlin Center, Mahoning Co., O., in the Town Hall on Friday and Saturday the 19th and 20th of January, 1883. All bee-keepers are invited to attend and send essays, papers, implements, or any thing of interest to the fraternity. A full attendance is requested of all who are interested. In fact, the meetings will be so interesting that you cannot afford to miss them. We expect a lecturer from abroad on the evening of the 19th.

L. CARSON, Pres.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in Temperance Hall, Freeport, Stephenson county, Ill., on January 16 and 17, 1883.

JONATHAN STEWART, Sec.
Rock City, Ill.

CORRESPONDENCE

For the American Bee Journal.

Half-Pound Sections and Supers.

DR. C. C. MILLER, 174-202.

So many different things have been said and planned about half-pound sections, that I am not surprised that my opinion is erroneously stated in the BEE JOURNAL, page 802. It is there stated that I think "about 10 to a Langstroth broad frame will be about right in size." Instead of that it should be "10 to the foot" of $4\frac{1}{4} \times 4\frac{1}{4}$ sections, that is, to hold a half-pound, the section could be $4\frac{1}{4} \times 4\frac{1}{4}$, and, so that in width, 10 sections would just measure a foot. This would make the section about one-sixteenth of an inch wider than Mr. Bingham calculates them. Very likely I expressed myself so bunglingly as to be misunderstood. But are we getting at the matter of size in the right way? If some one has used them, and found upon trial that a certain-sized section contains just one-half a pound, that is better than the figuring of a whole convention. If, however, no one has used $4\frac{1}{4} \times 4\frac{1}{4}$ sections, we can figure on the width to approximate the matter, and settle it finally only when we have referred the matter to the bees for actual test.

Although I may try half-pounds, I, for one, am by no means ready to adopt them, at least until I know more about them by actual use. Mr. Bingham, on page 802 of the BEE JOURNAL for Dec. 20, has ably given the advantages and disadvantages, but I think I see a possibility of some disadvantages not mentioned.

To begin with, most of us, or at least some of us, would have to go to considerable expense to get new broad frames if the $4\frac{1}{4} \times 4\frac{1}{4}$ size is used, for, the width being different, I should about as soon make new frames as to alter the ones that had been used for 1 or 2-pound sections.

If used without separators, the thickness of the comb might suit the queen so well that I can imagine such a thing as the whole brood-nest moved up into the super.

At present quotations we should be warranted in taking some trouble to change, but will there be any such permanent difference in price between pounds and half-pounds if anything like an equal amount of each is on the market?

Perhaps not one half-pound section was used this year for every thousand of one-pounds. Suppose the case reversed, and that a thousand half-pounds were put on the market for every one-pound, would not the one-pound section bring a higher price than the half-pound on account of its scarcity? There will probably always be a large class of customers who will think a thick piece of comb honey presents a finer appearance than a thin

one, and I suspect very few think otherwise.

To return to the subject of change of fixtures; there will be no change needed where the

HEDDON SYSTEM OF SUPERS

is used. In a private letter Mr. L. H. Scudder, New Boston, Ill., objects to Mr. Heddon's somewhat, saying, 1st, "I have little faith in being able to produce straight combs without separators." 2d, "If $4\frac{1}{4} \times 4\frac{1}{4} \times 2$ inches holds one pound of honey, will not a comb $\frac{1}{4}$ inches thinner be too light to suit all honest dealers?" I am pretty fully in accord with Mr. Scudder in his first objection, and yet Mr. Heddon does get straight combs. Whether he could succeed in my locality, or whether I could succeed in any locality, is an open question. With regard to the second objection, a section without separators must necessarily be thinner than one with, else it would be too heavy, and I am not sure that one-fourth inch is too much difference. But even if the section weighs less than a pound no honest dealer will object to that, providing he gets pay for just the weight he sells, and most of the dealers I know anything about sell in that way, and every one ought to. I have never been able to raise one-pound sections so uniform in size that they ought to be sold by the piece without weighing, for there is a variation, from lightest to heaviest, from one-fourth to one-half a pound in weight. The coming season I expect to try a few supers on Mr. Heddon's plan, and can then tell a little more about it.

Marengo, Ill., Dec. 22, 1882.

For the American Bee Journal.

The Blessed Bees Criticized.

JAMES HEDDON.

A New York visitor and bee-keeper, accidentally left a copy of a book having the above title on my table. Before sending it to him I obtained his permission to read it. I had heard several names mentioned as the author, or alias of "John Allen." I had been persuaded to believe firmly in the authorship of one of them. Since reading it I do not believe the one whom I had supposed did write the book.

I am now all at sea in regard to the matter. Say what I may, I can criticize none but the fictitious "John Allen." For the sake of what I believe to be important truths relative to our business, I will say what I am forced to believe. There is no sin in an unbiased opinion. There is no sin in publishing it where the motive is to benefit the class who read it. There is no cruel bitterness toward any individual, as I do not know who wrote the book.

The evident intent of the work is to add to other influences calculated to induce an influx into honey-producing, that of the fascination of the novel. If the author had, for his inspiring motive, that of assisting good and needy, but mentally and physically

enfeebled or otherwise unfortunate people, by inducing them to embark in what he considered so lucrative a business; that these otherwise possibly unsuccessful ones might succeed in securing to themselves the means of obtaining that higher mental, moral and physical culture that the good, the true and the noble so justly and wisely prize, then he has my most sacred friendship and sympathy. If, on the other hand, he is endeavoring merely to augment the income of the middlemen connected with our business (a thing which he is doing), he deserves the censure of every bee-keeper, as well as every good human being.

My own opinion is fully settled upon that point. I believe, from the tone and expression of the book, that the motives are good, and John Allen can rightfully be classed among the mistaken.

My experience as a honey-producer, together with the valuable lessons I have learned of others (nearly all in private conversation), forces me to believe, and my love of truth induces me to say, that it is my sincere conviction that the methods laid down are in exact opposition to the results given in the book entitled "Blessed Bees."

That this book is not only, like all other books, hardly ink-dried, until it is away behind the times, so fast does the practical part of our science progress; but it was not up with the times in which it was printed. That its author was not a practical honey-producer; that he drew largely from the writings of others and from their mistakes.

Referring to capacity, we have three classes of bee-keepers. The first and largest class are those who have from the least to the greatest amount of practical capacity, but no ability to convey their knowledge to others through the medium of ink. Then those who possess both, in moderate or extreme degree. Then those who have, in an eminent degree, the ability to tell four times as much as they think, and ten times as much as the experienced will believe, who have but very little practical dollar-and-cent knowledge of the subjects upon which they write. The more experienced always catch a gleam, if not a flood of light, revealing the true state of affairs in every sentence. This class write, but the younger practitioners, which make up our brotherhood, are of necessity led round about in circles by them, paying toll at every quarter pole.

To go on and show the whys and wherefores that connect the system of practice therein laid down, with certain failure, would require more space than we should occupy, and more time than we can afford to devote, and even to name them would double this already too long article.

The errors are: Returning Crates, Fall Breeding to Winter, Dry Cellars, Bees in the Fall and Spring at Same Price, Black Bees \$5 and Italians \$10 to \$20, High Prices of Certain Supplies, Best Honey Made by Italian Bees, Conditions of Successful Feed-

ing Back, Taking out One and Feeding Back Another Kind of Honey to Winter On, etc., to the letter box department.

It is not my province to contradict the large reports gathered together through several years and from all portions of the United States, and placed under the head of Notes, for none are more willing to admit the great possibilities of bees than am I, but attention should be called to the fact that these reports are uncommon, that they are nearly always from few colonies, excluding the possibility of coupling them with a future million-
aired condition for John Allen or any of us, and that the Grimms and Harbisons are not only so scarce that we quote them 15 years apiece, but the possibilities of Southern California, coupled with the experience of an old specialist, are not the probabilities of John Allen's three months of theory, and a bee book, in the pinneries of Northern Michigan.

We know that there are occasionally men who can get large and larger yields of honey from hundreds of colonies, thus putting their thousands of dollars' worth of honey into the market nearly every year, but these producers use methods never dreamed of in the philosophy of John Allen.

But the old adage, that there is "no roses without thorns," is not only true, but the reverse is also a fact, that there are roses among thorns, as this little book gives us evidence.

At the close of the work, on page 155, blossoms a rose whose name is *truth*. Though not beautiful to the sight of some beginners, some who have gone in on the plan of "bees work for nothing and board themselves," its sweet fragrance meets the nerves of every old practitioner, laden with memories of the happy past. I quote: * "So every person, who expects to get rich quickly by keeping a few bees, will fail. Money can be made only by thorough acquaintance with the business, and by careful, persistent work from year to year. But, in spite of what I say, some will get bitten by beginning bee-keeping without due preparation, and with false expectations. When you do get bitten please remember that 'I told you so.'"

Let us hope that the primary principles laid down in this book, when learned by the reader, will, in part, compensate for the errors in the general management, which he will soon have to unlearn, if he does not quit the business, broken in heart and broken in pocket.

For the American Bee Journal.

Md., Va. and W. Va. Convention.

The first annual meeting of the Union Bee-Keepers' Association of Maryland, Virginia and West Virginia, was held at Hagerstown, Md., Oct. 18 and 19, 1882. The meeting was called to order with President D. A. Pike in the chair, and J. Luther Bowers, Secretary. Thomas Foster was asked to assist the secretary. As the Association was not yet perma-

nently organized the secretary had nothing to report.

The standing committee on constitution and by-laws reported, through the secretary, the constitution and by-laws furnished by the AMERICAN BEE JOURNAL, which were approved by the committee and adopted by the Association.

The president's address was read by the secretary. In eloquent words our worthy president welcomed the bee-keepers of the three States to our Association, asking them to join with us in our discussions.

The members being slow to proceed to business, Wm. M. Bowers, of Illinois, said he was in the county and so came to the meeting; he was sorry to see the friends so backward and hoped they would take an interest. His remarks had the desired effect.

The election of officers resulted as follows: Wm. Anderson, of Harper's Ferry, W. Va., moved that the same officers hold over. Carried. President, D. A. Pike, Smithsburg, Md.; Secretary, J. Luther Bowers, Berryville, Va.; Treasurer, S. Valentine, Hagerstown, Md.; Vice Presidents, Thomas Foster, Cumberland, Md., Wm. Anderson, Harper's Ferry, W. Va., E. C. Jordan, Stephenson Depot, Va.

C. M. Hicks, of Fairview, Md., read an essay on transferring bees. On motion, he was given a vote of thanks for his address. After discussing the subject, the meeting adjourned until 7 o'clock, p. m.

Met at 7 p. m.; Vice President Wm. Anderson in the chair. Ten new members were added to the Association.

S. Valentine said that he aimed to have his queen-rearing colonies as strong as possible before commencing business, not giving any special method.

C. H. Lake, of Baltimore, asked if a queen that had been balled was of any account afterwards?

S. Valentine had seen queens that had been balled that did well afterwards. The general opinion was that a queen balled in a friendly way was seldom hurt, while if balled in an unfriendly, she seldom, if ever, amounted to much.

J. Luther Bowers asked if the Albino bee was not a freak of nature, or, in other words, would she reproduce bees of the same marking, one generation after another.

S. Valentine made a specialty of Albino queen rearing and said that they were a distinct race.

C. H. Lake said he thought they were a freak of nature, and said he had an imported queen on exhibition at the Fair, that produced a greater part of her workers of the so-called Albinos; thus proving that they were not of American origin.

Those taking an active part in these discussions were: Thomas Foster, Cumberland, Md.; Jacob Ebersole, Martinsburg, W. Va.; W. R. Young, Myersville, Md.; Wm. Anderson, Harper's Ferry, W. Va.; S. Valentine, Hagerstown, Md.; late of Double Pipe Creek; C. H. Lake, Baltimore, Md.; Wm. M. Struder, Millwood, Va.

Chas. H. Lake invited the Associa-

tion to meet at his tent on the fair grounds.

Adjourned to meet at Mr. Lake's tent, at 10 o'clock a. m. to-morrow.

Thursday, Oct. 19, 10 o'clock a. m. After examining the many exhibits of bee-fixings and bees, the Association was called to order. There being no further business before the Association, Hagerstown, Md., was selected for the next meeting.

It was moved to adjourn to meet at Hagerstown some time next summer; the secretary to notify members, and also to publish these minutes in several of the bee papers. Carried.

J. LUTHER BOWERS, Sec.

For the American Bee Journal.

A Standard Frame.

JAMES B. MASON.

The cry comes, from Maine to California, for a standard frame. Bee-keepers are beginning to awake to the fact that it is one of the most essential points, for the advancement of bee-culture, that we have a standard frame, and a standard section-box. The latter we have secured in the $4\frac{1}{4} \times 4\frac{1}{4}$ section, but as to a frame we are, as yet, "terribly mixed," and I believe, until we settle on a standard frame, we shall not make any very decided advance in bee-culture. Ever since Mr. Langstroth gave us the movable frame, the country has been flooded with patent hives, containing frames of different sizes; the inventors claiming great advantages thereby; but, on the whole, has any great advantage resulted from the use of the different sizes, over the regular Langstroth frame? It seems, that in the past twenty years, if there had been, we should have seen them, and if there has not been any, why will bee-keepers persist in using odd-sized frames?

G. M. Doolittle, one of the most successful bee-keepers, uses the Gallup frame; D. A. Jones uses the American frame; James Heddon uses the Langstroth frame; L. C. Root uses the Quinby, the largest of all. These men all appear to be equally successful, and I believe would be the same if they all used the Langstroth frame. It is my firm conviction that every invention that has been brought before the public, that has changed the size of frame, since the introduction of the Langstroth hive has been a detriment to the progress of bee-culture.

Mr. Heddon did not claim but that there were other frames, in and of themselves, as good as the Langstroth, but he thinks the Langstroth is as good as any, and believes it to be "the coming frame" and changed our 50 hives so as to fall into the beaten track, and use a standard frame, and he thinks he made money by it. When bee-keeper are willing to follow his example and give up their pet notions, then bee-culture will advance rapidly.

How is the adoption of a standard frame for America to be brought about? I do not know just how it can be done, but will advance a few thoughts, and leave the subject for more able hands. The able corres-

pondents should write more on the subject through our bee papers; conventions should canvass the matter and resolve to accept some size of frame as a standard, and their influence will go a long way toward establishing a standard frame. Supply dealers should stop advertising to manufacture all sizes of fixtures, and thereby save themselves trouble, and their customers money. I would not be understood to discourage invention, let us have all the improvements in our hives possible; then if they can be improved, all we shall have to do is to lift out our frames and hang them in the improved hives. Carriage makers would not think, for a moment, of changing the width of carriages in their new styles, nor should hive manufacturers change from the standard size.

Mechanic Falls, Me., Dec. 19, 1882.

Read at Eastern N. Y. Convention.

Honey as a Staple Product.

A. J. KING.

Mr. President: The subject assigned me by your committee, is one of vast importance, and I cannot but regret the limited time I can give to its consideration. It is the question which has been propounded to the promoters of all other industries in their incipient stages. When the bill was passed in Congress to establish the first line of telegraph, requiring an appropriation of \$30,000, it was argued by many, even allowing the thing would work, so few would make use of it that years would elapse before it would pay for the appropriation. The thousands of miles of telegraph and telephones all over the world, all paying handsomely, attest the folly of such suppositions. When the elevated railroads of New York city were first talked of, it was thought by many that it would be so much capital sunk, for, nobody, but a few "dare-devils" would ever risk their lives by riding on them. To-day they are over-crowded with men, women and children gliding along at lightning speed, as unconcerned as if in their own parlors at home, and these roads are paying institutions.

About twenty-five years ago, when the grape question was up for discussion and vineyards were springing up in many parts of the country, the "wise acres" prophesied an overstocked market and a general collapse of the entire business. The "collapse" never came, but the grape crop of the country has increased since that time a thousand fold, and is to-day one of the recognized industries of leading importance in a large part of our country.

So we might go on, until we had outlined the history of nearly every business depended on for a livelihood. We should see them in their small beginnings, gradually expanding, passing their experimental phases, and finally attaining the rank of "necessities." This gradual development seems to be necessary in art, science, mechanical inventions, or in new art-

icles of food, in order to educate the masses to receive them.

Within the last fifteen years the production of honey in the United States has increased ten fold, or, in other words, from ten millions to about 100 millions of pounds, and yet the average prices paid for it have not diminished, and why? simply because the people have been educated to its use. Through the influence of conventions, honey exhibitions at fairs, bee books, bee journals, etc., the masses are beginning to realize that honey is the most healthful of all the sweets; that when properly used it surpasses all others in preserving and adding to the delicate flavor of all fruits; that in the preparation of medicines it has no equal. The baker and brewer also are beginning to use extracted honey, where formerly they used sugar and glucose, but the greatest and best use to which it is put is on our tables, where, in many instances, it is taking the place of the different brands of syrups.

The subject has been so widely discussed that all the agricultural papers of any value have found it necessary to devote space to this subject. Many bee-keepers who, a few years ago, had no home demand, now find it necessary to reserve several thousand pounds for this purpose.

With all these influences at work, there is yet probably not one person in ten, especially in our cities, in which honey forms any part of his diet, not because he does not or would not like it, but simply from the fact, that either the information of its merits above other sweets has not yet reached his ears, or he is yet ignorant of the channels through which he may procure a pure article at a reasonable price. The great bulk of our honey is sent to the cities, consigned to a few houses, who do not retail or take any pains to let the masses know that they keep honey for sale; but, instead, they sell it to grocers who retail it at prices which make it cost the consumer fully double the amount which the producer receives for the same honey. Honey, at such prices, must be classed among the luxuries, to be indulged in only occasionally, except by the wealthy.

Again, some large producers, by the offer of cash down or small advance above regular prices, will sell to those who they have every reason to believe will use it to give flavor to double the quantity of glucose to be palmed off as "choice new honey," thus, vastly increasing the volume, but correspondingly reducing the price and degrading the merits of the pure article, greatly to the disadvantage of the producer and to the detriment of the industry. Of course, the unscrupulous mixer can well afford to greatly undersell all honest dealers, as two-thirds of his mixture costs him only about three cents per pound. Were this abominable practice to be permitted to continue, the production of honey would be indeed a precarious business, but, thanks to the good sense of our people, by the aid of our conventions and numerous publications on bees and honey, assisted by the press

of the entire country, the alarm has been sounded, and laws have been and are being passed against the crime of adulterating food products, which are even now producing the most salutary results. The great factories recently erected for the production of grape sugar and glucose have many of them shut down and all are in a fair way of collapsing at no distant day, through the influence of further legislation on the subject.

Now, I fully believe that with this enemy disposed of, extracted honey, averaging the grades, can be made to net the producer ten cents per pound; and comb honey about fifteen cents per pound, and I as fully believe that, with our present knowledge and appliances, honey may be produced with fair profit at these prices. I speak more confidently with reference to extracted honey which will, in all probability, be the main supply for the future. Now this honey ought to reach the real consumer, after all freights and commissions are settled, at an advance of not over five cents per pound, or 15 cents for extracted and 20 cents for comb honey.

If the consumer and producer can be brought as nearly together as here indicated, and still more vigor be used in acquainting the public with the merits of honey, there will be practically no limit to the sales which may be made. It is estimated that if the amount of sugar and syrup annually consumed in the United States could be equally divided among all the inhabitants, each would receive between thirty and forty pounds. Now, suppose that each individual should consume but ten pounds of honey, and we have the enormous amount of 500,000,000 pounds at once disposed of, or nearly five times the present population. Add to this the increasing demand for extracted honey for manufacturing purposes, and the continually widening and ever extending demand for American honey in foreign countries, and the outlook for bee-keepers becomes pleasing to contemplate.

Another use to which honey has been recently put, bids fair to greatly increase the demand for it. I refer to the experiments of C. J. Quinby Esq., of White Plains, N. Y. He has, during the past three years, produced a wine in considerable quantities, rivaling in fine and delicate flavor the best imported brands, and used nothing in its production but pure honey, of any variety. Very little of his wine has been kept over eighteen months, for the reason that the demand is greatly in advance of the supply. He sells it for communion services and medical use, as the best physicians in his town recommend it. We do not refer to this because we favor the wine industry (for we aim to be temperate in all things) but only to show what will, in all probability, at no distant day, consume a large quantity of our surplus extracted honey, especially the darker varieties. What would be the state of the grape market to-day if the production of wine should suddenly cease? Now, assuming that wine made from honey

is as good as that made from grapes, that one gallon of honey will produce at least two gallons of wine, worth at the very lowest estimate, \$1.25 per gallon, it is easily seen that the manufacturer can use 10 cent honey and yet make a large percentage on his investment.

Thus we have endeavored to give some of our reasons for believing that extracted honey, at least, will become a staple article in our markets, so soon as the supply may be relied upon to answer all the demands which will be made upon it, and this rests entirely with the producer. Comb honey will likely continue a luxury, as long as producers treat it as such, by reducing the sensible one-and-a-half and two-pound boxes down to those containing a mere mouthful.

New York, Jan. 1883.

For the American Bee Journal.

Wood Separators for Small Sections.

J. C. NEWMAN & SON.

Having read with much interest the proceedings of the Michigan State Convention, and also the article on page 802 of the BEE JOURNAL, we will state something of our experience in the use of small packages for comb honey.

In the season of 1878 we decided to use small sections for honey, the size being, if we remember rightly, $3\frac{1}{2} \times 3\frac{1}{2} \times 1\frac{3}{4}$, and without separators. The sections were filled complete with foundation and we supposed we were sure of having them all very perfectly filled, but, on taking them from the hives, the very opposite was the case. The worst of all was the difficulty of putting into the crates; but, after much patience, it was completed, and shipped to Thurber & Co., of New York, with very good results.

It took but one season to decide that it was utterly impossible to produce a fancy article of comb honey without the use of separators, even with small sections and the use of comb foundation. After the above experience we decided to adopt a very different plan, which was as follows: To change the size of package and use them on the same section racks that we used for other sizes; which would necessitate a size $3 \times 3\frac{1}{2} \times 2$ to hold exactly one-half pound, and right here we will say that we have put up many hundred crates of fifty sections, weighing from 24 to 26 pounds.

We use separators of very thin wood, and we are very particular to take the honey from the hives as soon as finished, for the bees will soil the small packages very quickly.

In the season of 1880 we produced about 6,000 of the half-pound sections of honey, and made a sample shipment to Voigt, Mahood & Co., of Pittsburgh, with returns at \$6.75 per case, and an order for all we had, at the same price, stating that it was the neatest article of the kind that had ever been placed on their market. The past season we made a sample shipment to Crocker & Blake, of Boston, with returns at \$7

per case, and saying it was the finest of anything they had ever had.

The only objections to Mr. Bingham's $4\frac{1}{2} \times 4\frac{1}{2}$ would be the extra expense of foundation, and the combs being so very thin. Would the bees work out the wax as well, or would they leave the (so-called) fish bone in the center? And, also, would not the time occupied by the bees in capping so large a surface, for so little honey, be a more serious objection?

After an experience of four years with the half-pound sections, and for the benefit of those who are about to begin their use, we will say that the coming season we shall again change our package, which will be $3\frac{1}{4} \times 4 \times 1\frac{1}{2}$ for the following reasons: It would give a better-sized comb for cutting up, and the combs, being thinner, the bees would fill out better around the outside, next to the wood.

Unless properly adjusted to the hive, and very particular attention is given, the yield per colony, will be very much less than if larger-sized packages were used. If any of the brother bee-keepers used half-pound sections before 1878, let him report through the columns of your very valuable BEE JOURNAL.

Peoria, N. Y., Jan. 1, 1883.

For the American Bee Journal.

Bee-Keeping in Nebraska.

WM. STOLLEY.

I started "Apiculture" here, 150 miles west of the Big Muddy (Missouri River), three years ago, with but two rather weak colonies of black bees, without having at that time the slightest knowledge of them. As was to be expected, under such circumstances, I blundered in my first summer's management, viz.: increasing from 2 very weak, to 3 still weaker colonies in the fall, but with very little honey for winter stores.

Then I got hold of the excellent BEE JOURNAL and found how far I was missing the mark. But, following strictly its teachings, I succeeded in providing, in time, my bees with the required winter stores, by feeding night and day with coffee A sugar syrup; and, in the spring of 1881, I found to my great satisfaction that every colony was alive, although seriously afflicted with dysentery, and two of the old queens dead. So I commenced the season of 1881 with 6 colonies, and, aided by the use of comb foundation, I increased to 14 colonies that season, and obtained 230 pounds of extracted surplus honey.

Meanwhile, I procured, of Rev. A. Salisbury, 4 tested queens, three of them Italians and one pure Cyprian; all of them were properly introduced before cold weather set in, in 1881. Only 2 of these queens proved suitable for breeders; and, in particular, the Cyprian queen outstripped all the rest. She proved to be, not only exceedingly prolific, but her worker bees are also amiable and the best honey gatherers. From these 2 queens I have reared 20 queens in 1882, of which 17 are Cypri-

ans and but 3 Italians, allowing no drones to be reared in my little apiary but in the Italian colony; hence, all my Cyprian queens were mated with Italian drones.

The spring of 1882 found me as the owner of 12 good colonies of bees, viz.: 1 Cyprian, 1 Italian, and 10 black and hybrids; since 2 colonies had lost their queens during winter, and I had to unite the queenless ones with other colonies.

With the aid of 4 additional Italian queens bought, one from G. M. Doolittle, one from Chas. Dadant & Son, and two from Scovell & Anderson, the aid of 70 lbs. of foundation, and the pasturage of one acre of melilot clover, I increased to 38 strong colonies in the fall, and obtained 520 lbs. of extracted, and 80 lbs. of comb honey, in 2-pound sections, which I readily sold at 25c. per pound.

Towards the close of the season I lost my Doolittle queen, after I had reared 4 queens from her. I also reared 4 queens from the Dadant, and 2 from the Scoville & Anderson queen. I have superseded all my black and hybrid queens, except 3, which proved to be the best of that race of bees, as I desire to winter them once more, and compare results next spring.

About the middle of October I finished packing my bees (inside the hives) with woolen blankets and chaff, and about the middle of November I moved them back to the rear wall of my bee-house, and packed them in prairie hay, sheltered the entrance with slanting boards, and then covered the whole 2 feet thick with prairie hay. On December 17 my bees had their last flight, and I hope that they will pull through the winter all right.

Whether bee-keeping can be carried on successfully, in this, the so-called "Desert of America," I consider practically solved. At least, I have got the requisite confidence to persevere, and my little success has already inspired others, who will try their hand at it during the coming season.

I have partly sold, and partly ordered 12 colonies at from \$12 to \$15 per colony, the risk of wintering to rest with the purchaser, and, with the proceeds, I propose to build a honey-house in addition to my bee-house, 80 feet long.

Our lands are cheap, and melilot, matrimony vines and borage will always do well with us, hence, what should hinder us from becoming successful apiculturists? I now have $1\frac{1}{2}$ acre of matrimony vines well established, which will feed my bees from early spring till frost. Near me, are about 20 acres of melilot (*Melilotus Alba*) which are entirely devoted to bee pasturage and also 1 acre of borage.

We are preparing another bee-farm on a larger scale, on the Loop River, where 50 acres or more will be sown with melilot, and as many acres with matrimony vines as can be grown with plants obtainable; and as soon as ready, we propose to put the bees there, and do not care much about white clover, basswood, etc.

I predict that "the Desert of America," will count big, in the near future, as a honey-producing section of this land of plenty, and the AMERICAN

BEE JOURNAL will count its subscribers from the "far West" by hundreds. I will send you the names of parties who become practically interested in apiculture as fast as the nucleus apiaries originate here.

Grand Island, Neb., Dec. 28, 1882.

For the American Bee Journal.

The Folly of Too Small a Section.

L. H. SCUDDER.

I have read with care the remarks of Mr. T. F. Bingham, the editor, and others, on page 802 of the BEE JOURNAL, and will try and give you some of the reasons why I think we, as honey-producers, should not advocate the use of a continually decreasing size of package for honey. In the first place, neither dealer or consumer would require us to go below a one-pound section, if we did not induce them to by placing it before them; but we, in our anxiety to outstrip our neighbor in the production of an article which will appear nicer and, by that means, sell more rapidly and for a shade higher price, continue to reduce the size of sections until (if this folly is continued) honey cannot be produced with sufficient profit to justify a person of ordinary intelligence in engaging in the business.

We know from experience that honey consumers will not be willing to pay a high price, because of the novelty of the package. What was more attractive in appearance than the glassed section, and still, how short-lived it was? Glass at 25 to 30 cents per pound was more expensive food than consumers could afford; and buying wood at similar prices will become burdensome when we get to using about as much wood for one-half or one-quarter of a pound of honey as we are now using for one pound.

I cannot view it in any other light, than that honey-producers are working against their own interests, in advocating the use of a smaller package. Let me give you a few reasons why I think so.

1st. We must discard all our material left over from last year, which to some of us is a considerable item.

2nd. Make new supers, which means money, whatever style we see fit to adopt.

3d. Double or quadruple our expenses for comb foundation.

4th. Compel the bees to use double the amount of material for capping, and requiring additional time to perform the labor.

5th. Doubling or quadrupling the labor in the manipulation of the sections from the preparation to the final packing for market.

Is it not clear that this additional labor will compel many of us to carry a decreased number of colonies? I see no other way, for the very important reason that competent help cannot be obtained; at least, that is the case in my locality, and I presume it is so in many others.

Now, taking this view of the case, how are we, as bee-keepers, to manage to win bread for our families? Some

times, for years in succession, the crop will be light, and our profits small, barely sufficient to maintain our families; then, perhaps, a perfect deluge of nectar will come, every shrub and flower bending beneath its weight, and as our busy little workers come rushing home, laden to their utmost capacity with their precious freight, would it not be interesting to watch us "Progressive Apiarists" undertake to measure and store away the fruits of their labor in half-pound sections.

Truly, the prospect is not flattering; it seems to me that it would be a hopeless task, and I, for one, cannot see my way clear to undertake it. Call this "croaking" of an old fogey, if you see fit; I care but little; if the business ceases to be profitable, dearly as I love it, I will turn my hand to something else.

New Boston, Ill., Jan. 1, 1883.

Read before the Maine Convention.

Bee-Keeping for Ladies.

ISAAC F. PLUMMER.

I have thought perhaps it would not be out of place to give you a few thoughts on bee-keeping as an employment for ladies; as I know there are a number of ladies in our State who are interested in bee-keeping, and I have often thought that bee-culture and its benefits have never been properly or fully presented to ladies as a light and profitable employment.

The subject of bees and flowers is so inexhaustible, so full of interest, indispensable to each other, and each so well adapted to the care and cultivation by ladies, that a few hints on this interesting subject may lead to others still greater.

Bee-culture, like all sciences, is full of opportunities for research, and I think, even more interesting; and, in fact, there is a certain mystery about the habits of bees that forever keeps the imagination waiting for some new discovery or development.

The great drawback to bee-keeping has been stings, but modern improvements in bee-culture, such as bee-veils, gloves and bee-smokers properly used should be sufficient to forever dispel every fear even of the most timid.

Bees have been spoken of from the earliest history of the world, and we often see them alluded to in the Bible, and bees and honey in those days were spoken of as possessing wonderful virtues. Some of the greatest writers in the history of our world mention the honey bee as being a gift of the gods, and so I am led to believe that many a silent lesson in the economy of the world has been learned from the wonderful bee. We never forget that sweet and simple song:

"How doth the little busy bee
Improve each shining hour."

It teaches us that the sweets of this life are offered to us all as freely as the sweets of the flowery kingdom to the virtuous and industrious bee. If we but imitate these virtuous habits our coffers will overflow with the sweets of life. In fact, the whole study

and practice of bee-culture is refining, ennobling and elevating.

Ladies are certainly adapted to bee-keeping, because, as a general rule, they love and cultivate flowers, the very perfection of virtue and inspiration; and bees and flowers seem inseparable. Where flowers are, bees are; even in the deserts where the foot of man has never trod. In the cliffs, on the hills, and in the valleys may be found the industrious little bee, sipping the sweets from the many flower that are

"born to blush unseen,
And waste their sweetness on the desert air."

What a wonderful mission these little workers seem to perform while gathering honey, which the Bible declares is "sweet to the soul, and health to the bones." They spread from flower to flower the germs of life of the sweetest things of earth's broad bosom. Let us provide abundant forage for our bees, fill our gardens full of flowers and thus invite them to come and taste of the nectar which the flowers produce within our bowers. I would not advise all ladies to keep bees; but to those who have time, inclination, and wish all the benefits, including the profits of bee-keeping, I say, try a few colonies. Give them the same care and attention you give flowers, and I am sure the results will exceed your most sanguine expectations. Some of the smartest bee-keepers we have in this country are ladies, and I see no reason why the ladies of Maine cannot be as successful in this branch of business as ladies are in other States.

SELECTIONS FROM OUR LETTER BOX

Smartweed and Hearts-ease.

The past season has been the best of the past four years with us. My bees gathered pollen from the hazel nut, and, perhaps, from soft maple as early as February. During April and May bees could do but little, on account of cold and wet weather. I fed mine; had I not, many of them would have starved. The principal flow of honey in Southeastern Nebraska was from the smartweed or hearts-ease, of which there is an abundance growing up among the corn after the farmer has finished cultivating it; also growing thick on wheat and oat stubble, after harvest, or by the way side, everywhere, nearly, except on the prairie. There are several varieties of this weed which yield an abundance of honey superior in flavor to the well-known basswood. I have both kind, and most of my customers prefer the hearts-ease honey. This plant blooms from the 1st of August till frost. My bees commenced swarming in August, and continued to swarm until late in September. One swarm of Cyprian bees came out the last of August. I lived them in the Oatman Modest Hive, gave them 1 frame of brood and the

remainder of foundation. I put on surplus boxes, and closed the hive. This swarm gave me about 30 lbs. of comb honey, besides building out and filling the brood-chamber completely. Cyprian bees color their combs more than the German bees. I think they work over all the old comb they can find; besides, they are not careful about the quality of propolis they use. One colony used black paint from barbed wire fences, and their combs were as black as pitch, and had the odor of coal tar. P. BOLINGER.

Salem, Neb., Dec. 22, 1882.

An Average of 57 Pounds per Colony.

It has been a very hard season here for bees, a year ago this fall I packed 29 colonies in sawdust, with chaff over the frames; when spring came they were all alive, but one was queenless, which was united with another weak colony. I succeeded in bringing the 28 colonies through the cold, late spring by feeding a little over 100 lbs. of coffee A sugar. My increase was from 28 to 44, mostly by natural swarming. I also had two swarms leave for parts unknown. I took from them 850 lbs. of comb and 750 lbs. of extracted honey, which gives an average of a little over 57 lbs. for each colony in the spring. My honey was sold here in Scranton, the comb for 16 cts. per lb. and the extracted for 14 cts.

C. E. MILLER.

Industry, Pa., Dec. 20, 1882.

Paste for Honey Labels.

Please state, through the BEE JOURNAL, how to make mucilage or paste that will hold labels on new tin. I have tried a mucilage of gum arabic, but it is not a success.

WM. ROBERTS.

Vaughansville, Ohio.

[This question has been overlooked for some time; we will now answer it. Mr. C. Haucke, of Kentucky, gives the following, which he avers will be successful: "Make a thin batter of best buckwheat flour, stir this in boiling water, on a slow fire; when cooked, or thick, take it from over the fire, and, to each quart, stir in 2 oz. of New Orleans sugar or molasses, while hot. Keep in a cool place. This paste will stick as well to a non-porous surface as to a porous one.—ED.]

Last Season was the Best in 5 Years.

The season of 1882, after fruit blossoms came out, was the best for the past 5 years, for bee-keeping, in this locality. Bees commenced swarming and gave one swarm each all round, during fruit bloom, which was the most profuse bloom ever seen in this section of the country. After fruit blossoms had gone, white clover came out in great abundance, yielding well. I obtained, on an average, 40 lbs. per colony of comb honey, in 1-pound sections, from white clover; and 20 lbs. per colony in 1-pound sections from basswood; making 60 lbs. per colony

of white honey in the comb. The fall yield was equally as good; my colonies storing 40 lbs. each, from buckwheat and goldenrod. I notice that some apiarists think buckwheat a poor honey plant; my experience is that it is one of the best honey plants we have. Last fall there was a field of buckwheat about a quarter of a mile from my apiary, the road being between the field and the apiary. I have repeatedly had people stop and tell me that the bees were swarming, such a roaring they made going to and fro from the buckwheat field. My bees are now all packed on the plan given by Mr. Heddon, except 12 colonies which I put in the cellar, for an experiment, having generally wintered on the summer stands. I think either Mr. Heddon's or Mr. Doolittle's writings are worth twice the subscription price of the BEE JOURNAL to any one keeping bees. E. W. WALES.

Disco, Mich.

Receipts for Cooking Green and Dried Fruits.

Please publish the following receipts and add to the pamphlet on "Honey as Food and Medicine."

GREEN FRUIT.—If mellow, use only extracted honey, it being the only liquid, it holds the fruit firm and gives a very rich flavor, sweeten or season with spices, to suit the taste. Cook slowly until done.

DRIED FRUIT.—Cook same as above, only add water enough to swell the fruit, after which add the extracted honey and spices, to suit taste. Cook slowly until done.

BRAY & SEACORD.

Warthan, Cal.

A Good Showing.

The past year has been one of the most laborious I have ever experienced, having the sole care of my apiary, and an orchard of 15 acres, of both large and small fruits, adapted to this climate; also superintending and working occasionally in an excavation for a fish pond, in my orchard, where there is a number of small living springs of water, affording a constant flow the year round. I am in hopes to finish it this winter, and shall stock it with the German carp in the spring. I commenced the season with about 40 colonies of bees, and by natural swarming, increased to 160; sold off 20 in the summer, and secured about 3,000 lbs. of surplus comb honey, leaving the hives with honey in store.

HIRAM CRAIG.

Fort Calhoun, Neb.

Italians vs. Native Bees.

As I have now got all of my bees into winter quarters, I will hand in my report. I had 175 colonies last fall; lost none; wintered on the summer stands, mostly black bees. I obtained 13,000 lbs. of honey, nearly all extracted. I have now 295 colonies; have 22 queens reared in 1881 from an imported Italian; got 1 imported Italian queen of Mr. Dadant, early in 1882 and I have about 40 queens reared from her; a part of them, I think, are purely mated. I think that I will

weed all of the blacks and hybrids out of my home yard, next spring, and run it with Italian bees. I think that I can rear them very nearly pure there, as there are no other bees within 4 miles. But I am not yet satisfied that the Italian bee is better than the blacks, taking all points into consideration. I intend to have one yard of them pure, and then watch them closely. I want to know which is best, as I think of going more extensively into the bee business. I shall make some chaff quadruple Langstroth hives, this winter, two stories high. I have one now that I made last year; it has 4 swarms of bees in it and I like it very well, it is the only Langstroth hive I have.

E. FRANCE.

Platteville, Wis., Dec. 4, 1882.

Strong Colonies Necessary for Success.

The spring was very backward, so that owing to chilled brood and other causes, my colonies were, if anything, weaker on the 1st of June than they were on April 1. This is my season's work: April 1st, 7 weak and 2 strong colonies; 9; Nov. 15, stored into winter quarters, 14 strong colonies with an abundance of stores. My crop is 600 lbs. extracted white clover; 200 lbs. extracted fall honey; 350 lbs. comb honey; total 1,150 lbs. My experience, like that of many others, is that the number of colonies is of less importance than their strength; and I have resolved hereafter to keep only strong colonies, if I can have but a single one.

F. P. BOUTELLER.

Belle River, Ont.

Wintering in Chaff Hives.

I had 98 colonies to start with in the spring of 1881; increased to 204; all in good shape for winter, and packed them on from 5 to 7 frames, in chaff hives with division-boards, with the open space filled with chaff, and a chaff box over the frames with muslin bottom and from four to six inches of dry oats chaff, and the whole hive, except the front, covered with dry hay. The winter was very open; the entrance being open all the time. They came through with less than 5 per cent. of loss. Now, then, I had two extremes of temperature, with bees put away just the same way, except that in one case the snow and ice effectually blocked up the entrance and in the other it was open. Now, my opinion is that chaff hives and chaff packing give a more even temperature and that the chaff box on top absorbed the moisture so that the bees were kept in a healthy condition. I have packed 58 colonies this winter in chaff hives with chaff division-boards 2 inches thick, with muslin on one side and $\frac{1}{8}$ inch boards on the other, with the muslin next to the bees.

G. ROUSE.

Wahoo, Neb., Dec. 21, 1882.

Glassed or Not.

Please state whether the small sections (1 or $\frac{1}{2}$ lb.) are expected to be glassed, for market.

A SUBSCRIBER.

[No. The crates should be glassed, but not the sections.—ED.]

Packed in Sawdust.

I commenced the season with 7 colonies, blacks and Italians (4 blacks and 3 Italians); increased to 27 colonies, and have them all Italianized; took 250 lbs. of extracted and 100 lbs. of comb honey in 2-pound sections. I use the Langstroth hive and pack them in sawdust, on their summer stands, similar to the plan of James Heddon.

J. W. SEARS.

Harrodsburg, Ind., Dec. 27, 1882.

Thickness of Wood of Small Sections.

In No. 51, page 802, of the BEE JOURNAL, Mr. T. F. Bingham gives the proper size to make half-pound sections; in doing so he did not give the thickness of the section, or inside measurement. Please give this in the BEE JOURNAL; I am only a beginner, but wish to keep pace with the most modern ways of bee-keeping. As this is the time for hive-making I also wish to get the best plan of making the top bar of the frames for fastening the foundation. I am making mine $1\frac{1}{4}$ inches, with $\frac{3}{8}$ above the sides and running a cut in the bottom $\frac{3}{8}$ deep, and bevel from the top $\frac{3}{8}$ to the bottom groove and then cut off one-half, thus leaving an open space in which to lay the foundation and tack on the piece that came out. I used them last season and found them to work very well.

GEO. ROGERS.

Hollin, Ont., Jan. 2, 1883.

[The thickness of the wood for the small sections is one-eighth of an inch. Many bee-keepers make the top-bars of broad frames as you suggest, and like them. It makes but little difference, so long as the top bar is stiff, and the foundation strongly fastened. Any way that will accomplish this, will do.—ED.]

Satisfied.

I had, in the spring, 9 colonies of hybrids and Italians; increased to 27, or 200 per cent., and obtained, of nice comb honey, 395 lbs., or 44 lbs. per colony, spring count, and did not buy a queen nor use any empty comb or foundation, and lost but little time out of my shop, attending to them. I sell all my honey at 20 cents per pound. I think there are about 200 colonies of bees in Wabash, and about one-half are blacks, kept in the style of our grandfathers; the other half are Italians and hybrids, kept in different sorts of movable frame hives, by different sorts of men, and I am the only one, as far as I know, that takes any bee paper.

J. COPELAND.

Allendale, Ill., Dec. 27, 1882.

A Question—Why Is It?

We are wintering 240 colonies of bees—80 colonies out doors in chaff hives, and the rest in an underground cellar. Those in the cellar are wintering well. The colonies out of doors are located in four different places; 18 at our home apiary, 10 three-fourths of a mile northwest, 14 two miles south, and 38 four mile south of home apiary.

These colonies were all prepared for winter in the same manner, were strong in numbers and well supplied with honey. The flora of the four localities is the same. The colonies in three of the localities mentioned are in a fine condition. The 38 colonies four miles from the home apiary are suffering badly with dysentery, and we shall probably lose nearly all of them. I would like to have you make the above statement in the columns of the JOURNAL and ask the bee masters to give a reason why the 38 colonies are affected and not the rest.

S. F. NEWMAN.

Newark, O., Dec. 29, 1882.

A Satisfactory Showing.

My bees in good order for winter. I have now 80 colonies, packed in chaff. I started in the spring with 50 colonies; they gave me 48 pounds of comb honey per colony. Those run for extracted honey, gave me 100 pounds per colony; which I sold at from $12\frac{1}{2}$ to 16 cents per pound and the comb honey at 16 to 20 cents per pound at home. The weather is mild; just right for bees.

J. H. KENNEDY.

Little York, N. Y. Dec. 28, 1882.

In Good Condition.

I began, in the spring, with 17 colonies of black bees; obtained 1,050 lbs. of extracted honey and 200 lbs. in the comb, in one-pound sections, and increased to 38 colonies, all in good condition for the winter.

WM. COLEMAN.

Devizes, Ont., Dec. 21, 1882.

Over 100 Pounds to the Colony.

I commenced in the spring with 54 colonies; increased to 80 and obtained 5,500 lbs. of honey, of which 4,500 was comb and 1,000 extracted. Our bees were in splendid condition for winter.

L. D. ORMSBY.

Pierpont, Ohio, Dec. 26, 1882.

Bees Enjoying Their Warm Quarters.

It has been a very poor year in this section for apiarists, bees having gathered no white honey and but a light yield of dark honey. But, nevertheless, I must have the BEE JOURNAL for 1883, all the same. I have 26 colonies in the cellar, evidently enjoying their warm quarters.

J. H. SHELTON.

Dorset, Vt., Dec. 22, 1882.

Mexican Clover for Bees.

My report for 1882 is as follows: Spring count 39, increase 28, total 67; sold 17. The average per colony for honey was about 30 lbs., in all 2,000 lbs. Owing to the cold weather, during the spring and summer, they did not do well. Cupalo gum yielded splendidly, but red rod was a failure; these are the only flowers that amount to anything. I have moved them across the river to where there is an abundance of white clover and poplar. I will try some sweet clover on the soil we have here, which is black loam. I have also some Mexican clover seed,

which is said to bloom luxuriantly, the season through. Has anyone ever tried the same, and is it a good plant? We will test it this season and report.

HEAD & BROWN.

Thebes, Ill., Dec. 20, 1882.

Likes to Work with Bees.

I like to work with bees, but, as for getting any profit out of them, we in central Ohio are far behind. I started last spring with 18 colonies, increased to 35; took about 175 lbs. of honey, mostly extracted; this makes a man feel as though he was a small potato, after reading some of the bouncing reports. Some of them certainly look a little fishy.

JOHN M. PARSON.

Tippicanoe City, Ohio, Dec. 22, 1882.

Packed in a Bee Cellar.

I started in the spring with nine colonies, and have increased to 19, by natural swarming, and have obtained 500 lbs. of comb honey, and 500 lbs. of extracted. I realized 15 to 20 cents per pound in my home market. I have them all packed for the winter in a bee cellar.

F. A. GIBSON.

Racine, Wis., Dec. 23, 1882.

Packed with Buckwheat Chaff.

I put into winter quarters, last year, 13 colonies, on the summer stands; one starved, leaving 12 to start with, last spring; they increased to 32. I took 800 lbs. of extracted and 200 lbs. of comb honey. I winter $\frac{1}{2}$ of them in the cellar and the others on the summer stands, packed with buckwheat chaff. They appear to be all doing well.

S. J. CHURCH.

Cedar Rapids, Iowa, Dec. 27, 1882.

Good Prospect.

I have been quite successful the past year, having averaged 100 lbs. of comb honey, per colony, spring count, and increased from 70 to 121 colonies. My honey was all gathered in the prize section, the largest number from any one colony that I remember was 106, which is about 200 lbs. I sold it at from 14 to 18 cts. per lb., mostly at Indianapolis. Our prospects for next year are good at the present time.

B. Z. SMITH.

Tuscola, Ill., Dec. 27, 1882.

Centralizing the Honey Market.

Bee-men ought to be combined and have but one wholesale house or dealer. The honey should be in a salable condition and all should be shipped to him. One dealer can handle all of our produce to advantage. Then the merchants will know where to send to get the lowest price, and we shall know where to ship our produce and get what it is worth. Then the market quotations will be alike in all the papers. I have 112 colonies in good condition. Bees have not gathered much surplus here for two years, but mine have been on the gain. There are some 400 colonies of bees in this county, yet we cannot supply the market. There has been some extracted honey sent here and sold for 20 cts. per lb.

CHAS. FOLLETT.

Osage, Iowa, Jan. 2, 1883.

200 Pounds from One Colony.

I shall pay more attention to marketing my honey hereafter, and want to adopt the newest methods for doing it. I could not get along at all without the BEE JOURNAL. Had it not been for, it I should have made a poor show at bee keeping, but, as it is, I have taken 9,000 lbs. of extracted and 110 lbs. of comb honey, as well as 200 lbs. of beeswax from 70 colonies in the spring and increased them to 130, in good condition, by natural swarming. They could have been increased to 200, had I the hives to put them in. The largest yield from one colony, was 220 lbs. of honey.

W. H. McLENDON.
Lake Village, Ark., Dec. 20, 1882.

One Continued Flow of Honey.

I commenced the season of 1882 with 20 colonies; 10 in Langstroth hives and 10 in box hives; transferred those in box hives to Langstroth hives on May 1. It being wet and cold, I had to feed until June 3, when the white clover blossoms began to "nod their heads at the bees," which are the Italians, hybrids and blacks. They soon took the hint, and we had one continued flow of honey from that time on. I increased to 45 colonies, obtained 2,000 lbs. of comb and 1,000 of extracted honey. The bees are in a good dry cellar, waiting for the balmy days of spring to come.

WM. HEALD.
Mt. Sterling, Iowa, Dec. 22, 1882.

Bees Pay Well.

I began the season with 14 colonies, 4 of which were transferred in May. One colony did nothing during the whole season, consequently I can really count but 13 available. I ran 8 of the colonies for extracted honey, with sections for side storing in several of them. I now have 30 colonies all put into winter quarters on the summer stands, packed in hay, and sheltered entirely from rain or snow, and protected on the west and north by a board fence. I had 10 swarms and increased 6 by division. Introduced untested 12 queens, 9 of which were successful, all producing apparently so far an excellent offspring. My honey product foots up, 781 lbs. one-pound sections; 234 lbs. bulk; 1,000 lbs. extracted; in all 2,015 lbs. really from spring count of 13 colonies. You remember, 2 seasons since, of selling me a queen: she produced beautiful bees and active workers. This season that colony gave me 234 lbs. of honey, and an increase of 5 swarms, the last of which came out on Aug. 27, filled the brood chamber and gave 22 lbs. of nice surplus comb honey. I think my net results would have been at least 1,000 lbs. larger had I given strict attention at the proper time. This does not near compete with some of the reports, but when coming from one who is not a practical bee-keeper, it gives you an idea what a man of average intelligence may do, even with the pressing duties of another business. I believe I can, in localities in this county, buy land cheap, and with 150 or 200 colonies, that have pasturage intelligently

prepared, make \$1,500 to \$2,000 clear money yearly, besides paying some attention to stock or poultry.

F. A. GROVE.
Kirkville, Mo., Dec. 30, 1882.

Size of the Half-Pound Sections.

After spending a few days with two of the brightest and most experienced bee-keepers in this country, I have settled, in my own mind, the size of section that I shall use to hold one-half pound gross, viz.: $4\frac{1}{4} \times 2\frac{1}{2}$ 13-16 inches plump, by $1\frac{3}{4}$, or, more exactly, 7 to the foot for separators, or $1\frac{1}{2}$ without. This measurement, $4\frac{1}{4}$, is adapted to the old length of fixtures, cases, broad frames, etc. The $2\frac{1}{2}$ piece is such a width as makes 3 fill the place of 2, $4\frac{1}{4}$, thus, 6 of them fill a broad frame in length. The $1\frac{3}{4}$ with, and $1\frac{1}{2}$ inches without separators, is such a thickness as will fit my case, 8 to the foot, but necessitates a change and addition of cases and partitions, using 5 instead of 3. For the broad frames it simply means cut them down $\frac{1}{4}$ in thickness and use separators. If I used broad frames at all I should surely use the separators. While this section is not adapted to either case or broad frames, just as they are, it requires an alteration that costs but very little in either capital or labor, and the comb it will contain will be one well adapted to storing and finishing rapidly, shipping safely and selling quickly. Do not be in a hurry to change from the one-pound section where you have them all in working order. You may be sorry if you do. Wait and see what the market says when plenty of both are there.

JAMES HEDDON.
Dowagiac, Mich., Jan. 1, 1883.

Bees in Good Condition.

My 58 colonies of bees are in good condition. Some gave me 28 lbs. of comb honey, and some 50 to 60 lbs. of extracted honey. I think any number of the BEE JOURNAL is worth to me all it costs for a year.

G. W. ASHBY.
Valley Station, Ky.

Abundantly Satisfied.

Just received the last number of the BEE JOURNAL for 1882, and I have it in the Emerson Binder, and on looking over the numbers, I cannot tell you how well satisfied I am, to think I have them all in, clean and snug. Without the binder, there would have been great risk of soiling the numbers, to say nothing of them being laid aside; but with the binder, all this is avoided. To all bee-keepers who do not take the BEE JOURNAL, I would say, take it for one year; you do not know the loss you suffer by not taking it; and to all who take the JOURNAL, and not the binder, I would advise, take it, you will never regret it. It will do more than merely satisfy you; if you have any phenological bump of order, you will be compelled to say and do as I advise; you will be compelled to acknowledge that you are abundantly satisfied.

EDWARD MOORE.
East St. Barrle, Ont., Dec. 29, 1882.

Queen Born without Wings.

In a letter published in the *Bulletin D'Apiculture de la Somme* just to hand, there is the following, which is interesting to all scientific bee-keepers: "Miss Josephine Chinni, of Bologna, Italy, a distinguished apiarist and queen breeder, has a queen bee which was born without wings, and, for all that, has been a very good layer of drone eggs, and worker eggs also. If you want to know more details, write her, and I do not fear contradiction."

ARTHUR TODD.
Philadelphia, Pa., Dec. 25, 1882.

Correction.

On page 809 of the BEE JOURNAL for Dec. 20, in the 10th line from the bottom of the first column, for the word "Heddon's," read Lowmaster's. Wagon Works, O. A. B. MASON.

Enticed to Take a Flight.

On Christmas day it was so pleasant that our bees came out from the hives. Next morning I found great numbers dead at the entrances. Was it so cold that they died before going back in? Or what? It would hardly do, would it—to open the hives and look in?

M. E. STEVENS.
Lebanon, Ohio, December 29, 1882.

[Of course, they became chilled and could not return to the hives. While the sun was warm—the air was very cold. They were probably old bees that would soon have died.—ED.]

Bees Pay Better than Stock.

My apiary, which remunerates for labor spent, is the best of anything yet. My 300 head of feeding steers and 250 head of fat hogs afford me no greater pleasure than my bees. The steers cannot compete with the bees for the amount of capital invested, and one is just as gentle as the other. I have hardly a steer but what I can ride, and my bees are just as tame, when necessary to get near them. I saw Mr. Jackson Woodward, of Mahaska county, who said that from 40 colonies this year he obtained 90 swarms, put back 60, leaving him 70 colonies, all told. From these he took 2,600 lbs. of extracted and 500 lbs. of comb honey. He is using the improved Langstroth hive, and is selling off all he has in the old form, at \$10 per colony. My bees fairly swarmed on my canning corn, this summer. I think it pays well to plant it for its honey qualities, if nothing more; but corn brought at the canning factory, \$12 per acre, after the bees were done with it. My buckwheat did well.

G. B. OLNEY.
Atlantic, Iowa, Dec. 23, 1882.

Honey Market at Home.

I commenced the season with 60 colonies; increased to 100 by natural swarming; obtained 3,000 lbs. comb honey, all stored in one-pound sections; sold it for 18 cts., wholesale, at home.

WM. COURTNEY.
Richview, Ill., Dec. 29, 1882.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES for 1883.

20 cents per line of space, each insertion,

For either the Weekly or Monthly Editions.

A line of this type will contain about 8 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

SPECIAL RATES.—Advertisements will be inserted in both Weekly and Monthly editions, at the following prices, if wholly paid in advance:

SPACE.	One month	Two months	Three months	Six months	One Year.
1 in. 12 lines	10.00	18.00	25.00	38.00	50.00
2 in. 24 lines	20.00	32.00	40.00	60.00	80.00
3 in. 36 lines	25.00	40.00	50.00	75.00	100.00
4 in. 48 lines	32.00	50.00	65.00	90.00	125.00
5 in. 60 lines	40.00	60.00	75.00	110.00	150.00
6 in. 72 lines	45.00	70.00	90.00	130.00	175.00

For the Weekly alone, 20 per cent. less than the above rates. On yearly advertisements, payments may be made quarterly, but must be in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Articles for publication must be written on a separate piece of paper from items of business.

CLUBBING LIST.

We supply the **American Bee Journal** and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club

The **Monthly Bee Journal** and any of the above, \$1 less than the figures in the last column.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Examine the **Date** following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

The BEE JOURNAL is mailed at the Chicago post office every Tuesday, and any irregularity in its arrival is due to the postal employees, or some cause beyond our control.

Attention is called to a few changes in our clubbing list for 1883, as given on this page. Those interested will please take notice.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but should be written on separate pieces of paper.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50. The Monthly BEE JOURNAL and either of the above for one dollar less.

Subscription Credits.—After sending subscriptions to this office, we would respectfully ask every one to look at the label on the wrapper of the next two papers, and there they will find the credit indicated thus: Those who have paid for the first six months of this year will find "June 83" after their names. Those who have paid for the whole year will find "Dec. 83" on their papers. The credit runs to the end of the month indicated.

The credit given on THAT LABEL is a sufficient notification of subscriptions due and receipt for payments made. If not so indicated within two weeks after sending money to us, you may be sure something is wrong, and should write to us about it. It will save annoyance and trouble if our subscribers will give this matter due attention.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 19th a. m., January 8, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The supply of extracted honey is fully up to the demand. My quotations are: 7c. for dark and 9c. for light, delivered here.
BEESWAX—It is quite scarce. I am paying 27c. for good yellow wax, on arrival; dark and off colors, 17@22c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand is good for extracted in barrels as well as in glass jars and tin buckets; arrivals are fair. The demand is fair for comb honey, which, however, is not cheap enough to make trade lively. Extracted brings 7@10c. on arrival; comb honey, 14@20c.

BEESWAX—Is scarce and brings 20@27c. on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey does not keep pace with the receipts. There is a large surplus on this market at present, and prices are from 2 1/2 to 3c. lower than last month.

We quote: white comb honey, in 1@2 lb. sections, 17@18c. Dark comb honey, hardly any demand. It is held at 12 1/2@15c. Extracted—White brings from 9@10c.; dark, 8@9c.; kegs, half-barrels and casks bring about same price.

BEESWAX—Choice Yellow, 30c.; dark to medium, 18@25c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Business in this line has been extremely dull the past week. Quotations are little more than nominal.

White comb, 17@20c.; dark to good, 11@13 1/2c.; extracted, choice to extra white, 8 1/2@9 1/2c.; dark and candied, 7@8c.

BEESWAX—We quote 25@28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull. Comb, at 16c. for large or hard to 18@20c. for choice bright in small packages; extracted at 8@9c.; strained, 6 1/2@7c.; choice, in smaller quantities, brings more.

BEESWAX—Prime bright steady at 27@28c.
W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Has changed in price a very little, we find it necessary to sell all grades about 1 cent per lb. less. Best white, in 1 lb. sections, 20@21c. per pound; in 2 lb. sections, 18@20c. Extracted is very dull indeed, hardly any sale.

BEESWAX—Scarce, 28@30c.
A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—There is only a moderate supply of choice to fancy white clover honey, and prices are still held firmly, though the demand is not large. Buckwheat and extracted honey continue slow.

We quote: White clover, first quality, 1 lb. boxes, 25c.; 2 lb. boxes, 23@25c.; buckwheat, 1 lb. boxes, 20c.; 2 lb. boxes, 16c. Extracted, white, 11@12c.; dark, 8@9c.

BEESWAX—The supply has been light and prime lots held a shade higher.

Western pure, 30@31c.; southern, pure, 31@32c.
D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—23@26c.
CROCKER & BLAKE, 57 Chatham Street.

Special Notice.

It gives me pleasure to announce that Dr. A. X. Illinski, of East St. Louis, Ill., and myself, have formed a co-partnership in bee-keeping, queen-rearing and supply furnishing. The Doctor is well known as an enterprising, progressive, and enthusiastic bee-keeper, of ample means. The style of the new firm will be "Flanagan & Illinski," and the management of the business will be conducted by myself as heretofore. E. T. FLANAGAN.
Belleville, Ill., Jan. 3, 1883.

Catalogues Received.—We have received copies of the following price lists for 1883:

James Forncrook & Co., Watertown, Wis.—"One-Piece Sections," etc.

Merriam & Falconer, Jamestown, N. Y.—"Apiarian Supplies" of all kinds.

J. S. Tadlock, Luling, Texas.—"Bee-Keepers' Supplies."

J. V. Caldwell, Cambridge, Ill.—"Supplies for the Apiary."

A. C. Nellis, Canajoharie, N. Y.—Catalogue of "Garden, Field and Flower Seeds."

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

It Pays.—I have sold all of my sweet clover seed. Advertisements in the AMERICAN BEE JOURNAL pay.

I. R. GOOD.
Nappanee, Ind., Dec. 24, 1882.

Pewamo, Ionia Co., Mich.

STUDENTS

IN BEE-CULTURE.

Having had such good success for two years past in teaching the theory and practice of honey-producing, I have now made arrangements to accommodate a large class during the coming season. I shall aim to give a five months' instruction, at the end of which time I hope and expect to turn out bee-keepers competent to profitably engage in the pursuit, or such as will be sought for as assistants, at wages above common laborers. All interested, write for terms.

BEE-KEEPERS' SUPPLIES

on hand, as usual. Beeswax wanted.
Dowagiac, Mich. JAMES HEDDON, 14w

“RED TAPE!”

Who will be the first to copy?
25,000 IN USE.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *volume* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit. by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur. by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Bienen Theory.—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine. by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market. including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Foul Brood. its origin, development and cure. By Albert H. Konnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dugan, giving in detail the methods and management adopted in their apiary. This contains many useful hints. Price 15c.

Bee Pasturage a Necessity. by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 25 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Muth. 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. Price 5 cents.

Bees in Winter. with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. Price 5c.

Queen-Rearing. by Henry Alley.—A full and detailed account of TWENTY-THREE years' experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price \$1.00.

Food Adulteration. What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35 c. postpaid.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Moore's Universal Assistant, and Complete Mechanic. contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 20,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Golders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measure, ready reckoner, plowing tables and many other miscellaneous and useful tables for farmers and others than any similar book ever published. Ask your bookseller for it. Sent post-paid for 40 cents.

Chicken Cholera. by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Deutsche Buecher, Ueber Bienenzucht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—
—Verrücktheit des Bienenstandes—
—Honig pflanzen—Erziehung der Königin—
—Gittern—Schwärmen—Ableger—
—Versehen—Italienisieren—Züfeger von Königinnen—Anziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellend über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigtuchen, Formfischchen, Puddings, Schaumkonfekt, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Conumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Bier und seine Krankheiten—Von B. N. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Fieberkrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

MENDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood case elegantly finished, 3 strings, 7 1-2 Octaves, full patent cantante agraffes, our new patent overstrung scale, beautiful carved legs and lyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

17 Our price for this instrument, boxed and delivered on board cars at New York, with one Piano Cover, Stool and Bench, only \$245.

Reduced from our late wholesale factory price, \$295, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Pianos, \$160 up. Over 15,000 in use, and not one dissatisfied purchaser. Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years.

SHEET MUSIC 1/2 price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

MENDELSSOHN PIANO CO.,

218miv

Box 2958, New York.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Rondellii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better.

I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Planting for Honey.

"Straws show which way the wind blows," is an old but true remark. We were reminded of this, when we noticed the following item in the Chicago Times of this week.

Bee-keepers are reaching the conclusion that to secure the best results they must cultivate honey-plants. Alsike clover is said to be equal to white clover. Buckwheat, basswood, the blackberry, and raspberry are all recommended for bee food. Catnip, motherwort, rape, mustard, sweet clover, and Rocky mountain bee-plant are recommended to be sown in waste places.

Planting for honey is getting to be a popular "song," and should be kept up until it is everywhere "sung"—and acted upon by those who have the care of bees.

The editor of the Daily Times of San Antonio, Texas, has been reading Cook's Manual of the Apiary, and the following is his opinion of it, which we find in the Daily Times of Jan. 8, 1883: "Till we read this book we thought bee-keeping a sort of side pastime, but we are now convinced that bee-keeping requires study and real work. Bees are good servants, but like many other servants they require a good deal of attending to. To those who keep bees this book is a necessity, and the sooner they buy it the better they will be pleased."

New Catalogues.—We have received the following Catalogues and Price Lists for 1883:

Thorburn & Titus, 158 Chambers Street, New York, Vegetable and Flower Seeds.

Cole & Brothers, Pella, Iowa, Flower and Vegetable Garden Seeds.

R. M. Morrill, Plymouth, Ind., Flower and Vegetable Seeds.

D. S. Given & Co., Hoopston, Ill., Given Foundation Press and Wiring Machines.

"The Bee and Poultry Magazine," is the new title of the paper published by King, Keith & Co., 14 Park Place, New York. The January number is on our desk and presents a neat appearance. It contains 20 pages devoted to bees and 10 to the Poultry Department. It is published at \$1.25 a year.

Mr. Frank Benton has again removed his residence. This time from Beyrout, Syria, to Athens, Greece—the ancient seat of learning, and mistress of the world.

The Bee-Keepers' Guide published by A. G. Hill, Kendallville, Ind., comes out in pamphlet form with the January number. It is much improved in appearance, and well filled with reading matter about bees.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Another "Kind Suggestion."

The following letter from Dr. A. B. Mason is just received, and as he wants to place the matter before our readers, we will let him "suggest":

DEAR JOURNAL:—On page 33 of the BEE JOURNAL for 1882 under the heading of "A Kind Suggestion," you say, "We are always pleased to receive suggestions or criticisms concerning the BEE JOURNAL, and hence give place to the following," from L. R. Jackson, Fairland, Ind.

"I like the size of the BEE JOURNAL much better than the old, but do not like the advertisements on the first page. We have become accustomed to look on the first page for the valuable editorials, and think the BEE JOURNAL would look much neater with all the advertisements at the back," etc.

When I saw the above I was very much inclined to "suggest," that the first two numbers of the Weekly BEE JOURNAL for 1882 were just right in that respect. Although I have several times been tempted to do so, I have not "suggested," but yesterday when getting the BEE JOURNALS for 1882 ready for the bindery, I thought, not out loud, I wish I had influence enough with the "powers that be," at the JOURNAL office to induce them to put the advertisements on the first and last leaves, so they can be removed when we want our JOURNALS bound. I have no use for 208 pages of advertisements in a bound volume that without them has 621 pages. Like Mr. Jackson, I like to see the valuable editorials, but if they are on the first page and that *should* get dirty I do not like it one bit, but if they are on the next leaf I can tear off the defaced one and have the editorials all bright and clean. I have taken the BEE JOURNAL for thirteen years, and except the volume for 1882, have them all nicely bound, and shall be glad when I get through tearing off leaves of advertisements and pasting on the loose leaves ready for the bindery.

A few days since one of your patrons told me he had heard more than a dozen speak of this very matter, so you see I am not alone in this "suggestion," and although many may think as Mr. Jackson does, and say so in the JOURNAL, still I believe if those that think as I do about this, were to hold up their hands we should have the "balance of power."

You know, Mr. Editor, that I do not run a "Growlery," and these are only "suggestions," and wherever the advertising pages may be placed I shall anxiously look each week for the safe arrival of my good old friend, the AMERICAN BEE JOURNAL, at Wagon Works, Toledo, O.

Jan. 5, 1883. DR. A. B. MASON.

Being satisfied that a "cover" for the Weekly BEE JOURNAL was a thing to be desired, at the beginning of the volume for 1882 we adopted that plan; but several who had become familiar with seeing the editorial matter com-

mence on that page, sent in their "protest," and, as above indicated, we changed the "make up" to suit them—but never changed our mind on the subject—though we try to please as many of our patrons as possible, whether we please ourself or not.

We hardly know now what to do, to test the matter: suppose we give from now till February 1st, to all those who want to "protest" against the change as suggested by Dr. Mason, to do so—and also for "approvals" of the present "make up." In this way we can "put it to vote"—and if we let the readers decide, the majority will "carry the motion," and the minority must be "satisfied." We are willing to do whatever our readers decide—and this is about the only way we can determine the matter. Reader, which way do you vote?

Mr. I. R. Good's Apiary.

The Nappanee, Ind., *News*, thus notices one of the industries of that town, the proprietor of which is well known to our readers:

OUR APIARY.—It is with pleasure that we notice this branch of our industries. It is owned by our neighbor, Mr. I. R. Good, who commenced in the business a few years ago, with a few colonies as an experiment, without any knowledge of the business. But in those few years, by close attention and posting himself, he has again proven the fact that an industrious specialist will always succeed, as his report for this season will show that bee culture will pay. Mr. Good has also become a rearer of the different kinds of queens, in the past year, and has had the best of success in sending them to his many customers in different parts of the United States and Canada, with comparatively no loss, through the mails, with his "Good" candy, as the different bee papers call it, which he makes himself; and from the many compliments he receives, it must be appropriately named.

He expects to be more able to supply his customers the coming season than ever. His report for the season, just closed, shows the following: Commenced the season with 145 colonies, and sold \$1,000 worth of bees and queens. Had over 2,000 pounds of honey. He has in winter quarters 225 strong colonies. We think this rather a good showing, and hope the same success will attend Mr. Good in the future, and we do not hesitate to say that those who deal with him will find him as appropriately named as his bee feed.

☞ We have a few copies of our pamphlet entitled "*Bee Culture*" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Do Bees Injure Fruit.

We have long tried to believe that they do not, but the following august authority traveling the rounds of the press, is conclusive evidence:

We once told Mr. Frederick Wilhelm Henerich Whokendemffeschaferponsky, a whole-souled Dutchman of our acquaintance, that bees did not injure fruit at all, when he pitched in and said he knew better, and gave the best argument we ever heard, that bees do injure fruit, in the following words:

"Vounce a long vile ago, ven I first to dis coundry come, I vent into mine abble orchard to glime a bear dree to kit some beaches to make mine yrow a blum budding mit; und ven I kits away up on de tobberrmost limbs, a hole lot of pees, pees vot come for honey gitten—dwo, dree five thousand of 'em come ven I vas on de highermost pranches, und tey sehting me all over so pad as never vas, und right before mine vace, too, und I not know vere I am, so I vall town from de lowermost limbs vay so high up, mit von leg on both sides of de bicket vence, und like to stove my outsides in. Vat you say, hey! pees no steal de fruit, ven I ketch 'em at it?"

We do not like to gainsay or resist such positive, convincing facts. We think the entire question may now rest without a quibble on this presentation of the case; it is so pure in language, thought and style, that it should be accepted as a model.

Honey and Beeswax in Russia.—The *Pull Mall Gazette*, of London, England gives the following on the results of unfair competition of beeswax with ceresin, in Russia, and its effect upon bee-culture in that country:

Among the latest victims of foreign competition are the bees of Russia. Under the influence of the free importation of a spurious kind of wax called ceresina, manufactured in Austria, the native industry is dwindling at a rate which threatens it with extinction. Of ceresina, which bears the same relation to genuine wax that oleomargarine does to dairy butter, no less than 1,000,000 pounds are annually imported, chiefly for use in the manufacture of tapers, which figure so prominently in all Russian churches. The price of wax has fallen under stress of competition with ceresina from 30 to 17 roubles per pound. At this price bees are regarded as hardly worth their keep, and in one district the honey crop has fallen from 15,000 to 6,000 pounds per annum. By the new tariff an import duty of a rouble a pound has been imposed on ceresina; but, according to the *Moscow Gazette*, it will have to be raised to 10 roubles to give the poor bees a chance.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

The Markets for Honey.

We have, for a long time, advocated the plan of bringing the producer and seller of honey into a closer bond of union. This would, if carried out to its fullest extent, no doubt, be found greatly to the advantage of the honey-producer, for this reason. Those more likely to understand the demands of consumers are those who are brought into contact with them most; and when settling upon a plan of marketing our crop, nothing could be more advantageous than to have the consumer, the merchant, and the producer all in perfect accord. The consumer to determine what is the most captivating and attractive, the merchant to ascertain the best packages to handle and sell, and the producer to decide upon the best plan to meet the views of the merchant and consumer.

Last summer, we noted the fact that the merchants were now reaching out after the most desirable crops of honey, and that Messrs. Thurber & Co., of New York, and Messrs. Crocker & Blake, of Boston, and others, were in search of fancy articles of honey, and that Mr. Ripley, of the latter firm, had given us a call, to enquire after some of the larger producers of honey. We were very much pleased with Mr. Ripley and his mission, and did all we could to forward it. We have just received the following letter from him, which gives his views of the honey market and will interest our readers:

THOS. G. NEWMAN, ESQ.—*Dear Sir:* It has been my earnest desire to write and thank you for the many courtesies that I enjoyed at your hands when in Chicago and Toledo, but we have had a good business, and that, to-day, means hard, honest work, and we have devoted ourselves to it to the best of our ability, and neglected you. I will endeavor to atone for past neglect. I have read, with great interest, the honey reports in your valuable journal, and the notice of my being in the West, which you kindly gave me, gave me an acquaintance with the bee-keepers of the country that we never dreamed of proving to us what our personal acquaintance has always shown, that bee-keepers, as a class, are ready and anxious to know anything that will improve their bees or bring them a higher price for their honey, and to accomplish that, what should they do? Subscribe to the *Weekly BEE JOURNAL*. As soon should a sailor go to sea without a compass, an astronomer be without a telescope, as a bee-keeper without the *AMERICAN BEE JOURNAL*.

We have had large consignments of comb honey from the West, and from

New York, and, from letters we have received, know that our consignors are well pleased with their Boston venture. We have had all of J. E. Crane's honey, of Middleburg, Vt., and it has all sold well. In our judgment, it is not well to put the price of any article too high; it drives trade away and it takes one season to make it popular again. We have noted, with anxiety, the discussion about the half-pound section, and find that the demand is credited to come from Boston, and we want to set ourselves right with producers in the matter.

In the first place, we want it distinctly understood that we do *not* advise any one to use the half-pound section exclusively. Mr. F. C. Benedict expresses our views on the subject perfectly in your issue of Jan. 3. No producer can afford to use half-pound sections exclusively. One-pound sections are small enough to please 95 out of 100, and producers must respond in this proportion. We sold J. C. Newman & Sons, W. S. Benedict and F. C. Benedict's half-pound sections, and rendered 30 cents per pound for all, and could have sold more, but the demand is limited.

Some dealers say they are too small; others say, one-pound sections are too small, and it is only for the variety that we may sell every man who comes along and wants honey.

Our demand for extracted honey is limited, and we are not able to get over 10c. per pound. Our demand for honey is falling off, and our advice to all is to market your honey early, be the crop large or small. What we mean by early is, before January 1.

Yours Respectfully,

FRANK L. RIPLEY,
of Crocker & Blake.
BOSTON, MASS., Jan. 6, 1883.

Honey in the Rocks.

The *Baltimore Sun*, gives the following, to illustrate the provident sagacity of bees. It says that in the mountains of old Virginia there is a mammoth natural bee hive, and that a lot of courageous youths captured the fort, killed the inhabitants and plundered the stronghold. It is a fine story, but lacks confirmation, and should be strongly doubted, unless more evidence is produced than that given by the reporter of the *Sun*. But here is the item.

Bee-trees are found widely scattered through the woods, and honey hunters make a business of felling trees, to which they trace the flight of bees. But now bee-rocks are being found where, in broad horizontal clefts, these industrious insects have for years been adding swarm to swarm, and accumulating vast yearly surplus stores of honey. The cells being hermetically sealed, the fluid never crystallizes; and floral bee pasture so abounds from February to December that not half the winter stores are consumed before spring flowers cover the heather and invite the bees to

feast on fresher sippings. The over-provident workers make no account of accumulations, but go on storing the same over-supplies year after year—a rare instance of imperfect sagacity.

For fifteen years people have observed bees flying towards the highest peak of the Butte mountain summit, 2,000 feet above their camp in Tehama county. They called it the mammoth bee hive. In October, a party of courageous youths undertook to climb the rocky ascent and make a raid on the great hive. They found what they expected, and proceeded to drill holes and blow up the rock. Instantly they were enveloped in a dense cloud of bees. Stung in every part, inside their underclothes included, they fled in dismay, and spent the night in repairing damages and preparing to renew the onslaught on the morrow, when, after a battle of three hours, they achieved a victory and captured the stronghold. The dead bees would have filled several grain sacks. The plunder consisted of one solid mass of honey in the comb, 5 feet long by 2½ feet by 3 feet in depth.

What Bees do in Georgia.

The *Monroe, Ga., Advertiser* gives the following account of an interview had by its reporter, with Mr. Wilder, abee-keeper of that locality:

"How is your apiary coming on?" we asked Mr. Frank Wilder.

"My bees are getting on nicely but they have not gathered honey to amount to anything in the last few weeks. The storm of the ninth of September seemed to stop the honey flow in some way or the other. At any rate my bees have not obtained much honey since then."

"Have you sold many bees this year?"

"Not a great many bees, but quantities of honey. I have made enough on my apiary to pay the provision bill of my family this year, and also the expenses of my farm."

We expressed surprise at this statement, but Mr. Wilder assured us it is a fact. "What is the biggest yield you have had this year from a hive?"

"I have one hive, from which I obtained three hundred and fifty pounds. I would not take \$50 for that colony. That is the biggest yield I ever heard of, except in one case. There is a man in Texas who reports seven hundred pounds as the product of one colony in one year. That is enormous and I never heard the like before."

"I have now fifty hives," continued Mr. Wilder, "and I cannot attend to them and do my other business. I believe I lost a thousand pounds of honey in September, by not being able to attend to the bees when they needed it. I intend to bring out a young man from Ohio next spring—if I can get the right sort of one—and put him in charge of my apiary; I am satisfied that I can make a deal of money by it."

CORRESPONDENCE.

For the American Bee Journal.

Bee Be-ing Busy.

I love to see the active bee,
I love to watch the hive;
When sun is hot, it lingers not,
But seems the more alive.

'Mid summer heat the honey sweet,
It gathers while it may;
In tiny drops nor ever stops,
To daily time in play.

From sundry lands with various bands,
Steady to instinct true;
Slight varied task or odds of haste,
It keeps one end in view.

With right good will and wond'rous skill,
It doth to work attend;
Each little cell is shaped so well,
That none its work could mend.

I hear it come, I love its hum,
Flying from flower to flower;
While to its store a little more,
Adding from hour to hour.

Example bright, its happy flight,
Presents to all around;
This lesson good if understood,
Is in its habits found.

Just so should I myself employ,
My proper work to mind;
Look for some sweet in all I meet,
And store up all I find.

Toronto, Canada.

For the American Bee Journal.

Who Shall Keep Bees?

DR. C. C. MILLER, 174-202.

Before me lies a letter from one who says: "As I have been troubled with an inflammation of the lungs for many years, I have been advised by prominent physicians to abandon my profession and work on a farm. But as I am no farmer and would be unable to earn my living on a farm, I thought I would ask you, as an expert in this line, if it would be profitable to invest in an apiary, where to get the best bees," etc., etc.

It is painful to think that to this and similar inquiries we can give no reply that we can feel sure may not mislead. To 9 out of 10 of every such persons it would be a real kindness to dissuade with all our power, while, perhaps, 1 out of 20, or 50, might be urged to embark in apistical pursuits to the abandonment of all others. But it is no easy matter to determine who may be the 20th or 50th one, hence it is a very difficult matter to give any honest advice without an intimate acquaintance with all the circumstances of the inquirer. I have blamed the editors of our bee papers in that the drift of the contents of such papers was to show the bright side only of bee-keeping, thus inducing into the business many not adapted to it, much to their after regret.

But I am not sure that the papers are at all to blame. All they can do is to publish such items of information as

come within their reach, and most of us like much better to send in reports of our successes than of our failures. It is quite flattering to my vanity to report: "I have, this year, commenced with 174 colonies, increased to 202, and taken over 8 tons of comb honey." Would I be as prompt to send in a report like the following: "This year I devoted my time exclusively to bees, commenced the season with 200 or more colonies; diminished by loss and doubling up, so that I had 162 colonies in the fall, and took, in all, 58 pounds of honey. By means of the business I am \$1,000 poorer than I was a year ago." Would the latter report be as much noticed and copied as the former? The former is a correct report of my success this year. The latter is just as correct a report of my failure two years previous, and I have no assurance that I may not have a similar report to make the coming year. In view of such possibilities, it is safe to advise that no one should go into bee-keeping, and give up all other business, until he has saved up enough ahead to support him at least one year without any income.

But suppose I hear of one who makes a success of bee-keeping, year after year, with never a failure, who has made thousands of dollars at it. Do I not hear of others who have made many more thousands in other pursuits? Shall I, then, give up bees and adopt the other pursuit? But you say, "It takes capital in other business and one can make a start with only a single colony of bees." Yes, you can make a start but you cannot make a living with a single colony, and with the price of it you can also make a start in merchandise, and, within a week, a friend was telling me of an acquaintance in New York whose net income from merchandising, the previous year, was a third of a million. "Oh yes," you say, "but the merchant had years of preparation, and special talent in his line of business."

Now, if you think no preparation and no special talent is needed to succeed with bees, you are decidedly in error. It is true, you can invest in bees to the extent of your capital, with no knowledge of the business, and so you can in merchandise, with a probability of losing in one as well as the other. As we are talking confidentially, I do not mind giving you a bit of my own experience. I am by no means as successful as many others, yet for the past more than 20 years I have been studying up the business, practicing and experimenting as much as I could whilst in other business; reading all the books and papers I could get about bee-keeping, and through all those years lying awake many a night, hour after hour, studying up plans for better success in the apiary. I have not yet reached that point where unsolved problems in bee culture are not plenty enough to baffle me. I am quite inclined to believe that those who have been the most successful in bee culture, if they had used their ability with the same enthusiasm in any other pursuit, would not fail of

success in that pursuit. In my own case, so far as financial success is concerned, I think I should be better off in this world's goods to-day if I had never kept bees. During the few years in which I have made it my exclusive business, I have made far less money than I did at other business in the same number of years previous. But, with my present views, I prefer it to any other business, because I can live in the country, be out-doors, have better health, be much of the time with my family, and I do not know of any other business I like so well. There is hard work in it, in spite of all that is said about it being nice for feeble invalids. The man that takes care of enough bees to make a living, will find he earns his bread by the sweat of his brow.

After all I have said, there are some who will find bee-keeping the most desirable of all pursuits. If you find it has so much fascination for you that you can take delight in lying awake nights studying about it, that you can stoically take the stings, even if they do sometimes wrench from you a groan; that you can come in at night during the busy season wet with sweat from head to foot and so tired that you ache all over, and not feel disheartened, and have, withal, tact and talent enough to conquer difficulties as they arise, then get the best weekly bee paper and if you can get some monthlies all the better; get a small number of colonies and grow into the business, or, better still, serve an apprenticeship with some practical bee-keeper and gain in one year the experience of many. Other questions as to kinds of bees, etc., you will find fully discussed in the papers and books (do not forget to get a good book), and I need not take time with them here. My chief aim has been to show some phases of the subject not generally dwelt upon.

The New Small Sections.

DR. G. L. TINKER.

Since sending you the article on the half-pound section I have received a letter from Mr. Manum on the subject and he thinks a section $3\frac{3}{4} \times 3\frac{3}{4} \times 1\frac{1}{2}$ will hold over one-half pound and that it should hold a little less than one-half pound, if anything, to suit the dealers. I then made little boxes to hold about the amount of comb honey that would be built in the several sizes given below, allowing one-fourth inch for passage ways on three sides of the comb, and, after filling and weighing, found that the size $3\frac{3}{4} \times 3\frac{3}{4} \times 1\frac{1}{2}$ would hold about $8\frac{1}{2}$ ounces, the size $3\frac{1}{2} \times 3\frac{1}{2} \times 1\frac{1}{2}$, $7\frac{1}{2}$ ounces, and the size $3\frac{1}{8} \times 3\frac{3}{8} \times 1\frac{1}{8}$ would hold just the one-half pound. Each size includes the weight of the section, which is about half an ounce.

I think that the section should weigh as nearly the half-pound as possible, and would therefore think it best to change the figures in the article to read, $3\frac{5}{8} \times 3\frac{5}{8} \times 1\frac{1}{8}$.

The size $3\frac{3}{4}$ I sent you a sample of is as small as will look well, but the $\frac{1}{8}$ off will not make much difference in looks. I first made two sizes, $3\frac{1}{2} \times 3\frac{1}{2} \times 1\frac{3}{8}$ and the one sent to you. I found the former a little too small and the latter a little too large, but thought it better to be as large as possible on account of the looks even though it would weigh a plump half-pound.

I have just read Mr. Heddon's article and find that he takes quite the same view that I do about the half-pound sections being 2 inches thick. If reduced to a size to hold just one-half pound the honey would not look well in any shape that it could be made, either in the section or cut out on the table.

New Philadelphia, O., Jan. 5, 1883.

For the American Bee Journal.

Northern Michigan Convention.

Robertson's Hall, Pewamo, Michigan, Oct. 10, 1882.—One o'clock p. m. The fifth annual Northern Michigan Bee-Keepers' Convention was called to order, and, in the absence of President Roop, Vice President George W. Stanton, was called to the chair. Roll of members called and a fair number answered to the call.

The annual reports of the secretary and treasurer were read and adopted as read.

Verbal reports were made by vice-presidents, Geo. W. Stanton, W. S. Pierson and J. H. Robertson, no others being present. President Roop, not being present, and no report being on hand, his report was passed for the time.

The minutes of the last meeting were read by the secretary and enrollment of new members was taken, enumerating thirteen at the opening. A recess was taken, after which it was resolved that the election of officers be postponed until, and made a special order of business to-morrow, at 10 a. m. J. H. Robertson drew up a list of subjects for discussion which was submitted and adopted.

The first subject was opened by J. H. Robertson, upon the "Best Race of Bees," who approved of home-bred Italians, and that hybrids were not objectionable as workers. He had reared from 300 to 400 queens this season, from home-bred queens of imported mothers; he has some Holyland bees, but sees no advantage in their introduction; has seen the Cyprian bees at Prof. A. J. Cook's, at Lansing, and, from what he saw of them, he thinks that they are bad to sting and are irritable. He thinks he has secured a good strain of bees from home-bred queens, especially strong to endure our winters.

O. R. Goodno spoke of his results with blacks, hybrids and Italians; he has always had the best results from hybrids; he avoids breeding black queens, but an Italian queen that produces hybrids is not objectionable. Has had the Cyprian and Hungarian bees, but too late in the season to test them and they died that winter.

Mrs. A. M. Sanders' experience was favorable toward hybrids. She bought

two colonies of Italians and two of blacks, and her hybrids did the best. From one colony of hybrids she had secured four crates of honey, 40 lbs. each, and one swarm, and from the swarm she had one crate of honey. She has no pure Italians now.

Mr. Robertson, in regard to the disposition of bees, says he has had just as cross pure Italians as he ever did hybrids.

W. S. Pierson had no experience with the new races of bees, but is of the impression that Cyprians are more cross than the blacks. He finds advantage in the Italians clustering on combs much better than the blacks, and concludes that Italians are good enough for him.

O. R. Goodno said he could subdue any colony with a good smoker, so that it will remember it and be submissive to handle afterwards. That was his experience two years ago with his best hybrid colony, and again this year, and he sees no injurious results from subduing them.

Mr. Robertson prefers the American bred queens. He does not keep queens over two years, unless they are of extra quality.

Mrs. Sanders had a queen over 4 years old, and considered her good yet.

Mr. Robertson thinks that in many cases where there is a queen 4 years or more old, there is another queen in the same hive, as he has found several instances where two queens occupied the same hive.

Mr. Robertson moved that it be the sense of this meeting that we rest content with Italian bees without the introduction of other races. Carried.

The next subject was "How To Breed Them," and was opened by Mr. Robertson upon his method of rearing queens. He gave the following plan: First, select the best colonies to breed from, remove one or more frames from the center of the hive and insert new combs or cards of foundation for the queens to lay in, and when full of eggs, he selected other strong colonies from which he took all unsealed larva and the queens, and, after eggs had been laid in the new combs, from which he wished to rear queens, in 4 days he cut off about one inch from the entire bottom of the new comb and passed his knife blade down through the sides of the comb and inserted the card in the middle of the hive, which he had prepared to rear the cells in, and from 60 to 70 cells would be started, and after 4 days he sorted out the best cells, not leaving more than from 8 to 12, at the most, of the cells, and the bees would carry the royal jelly from those destroyed to those retained, and those queens would hatch in 16 days from time the card was inserted; sometimes in 15 days. He would remove this card containing the ripe queen cells to his lamp nursery at 15 or 16 days, as the weather might be, and prepare nuclei, at same time, to receive the queens, and as fast as hatched he introduced queens to them; and where queens were not wanted sufficient to require a lamp nursery, he described how he made a wire frame that would go inside the hive to receive the card containing the cells; brushing off all

the bees and inserting the same in the wire frame. This being in the center of the hive would receive the proper temperature the queens should have to hatch; and with this frame in the middle of the hive, the sides could be covered with separate quilts and a woolen blanket over the wire frame, it could be visited without disturbing the bees in the hive, and, as the queens hatched, be removed to nuclei.

After Mr. Robertson's interesting description as to how to rear queens, it was agreed to adopt and try it next season. The convention then adjourned until 7 p. m.

At 7 p. m. the convention was called to order by Vice President Stanton. The first subject in order was "The Best Frame for all Purposes, Including the Hive."

Mr. Robertson spoke in favor of the Langstroth frame and against the Galup and advanced the theory that, for wintering, bees on the Langstroth frame worked their way from end to end of the frames, and, in a long continued cold spell in winter, did not have to move from frame to frame as they did in shorter frames, but only move along on the same; and for shipping, he liked them much the best.

Mr. Goodno has both deep and shallow frames in use, and much prefers the deep to the shallow ones, for convenience in handling, and for wintering, with a stick under the quilt to form a passage way, and prefers 3 pieces of bent hoop under the quilt to a straight stick, which has always served as passage ways for bees to pass from one comb to the other. All the Langstroth hives he had seen have a closed bottom board, which he dislikes, for many reasons. One is, in spring, when set out, he likes to clean out under the frames, and, with a movable bottom board, he can replace it with a clean, dry one, which is better than the old one; and with a movable bottom board any hive may be used as a second story, while without, you must have an extra set of upper stories. In very hot weather, in summer, he has had bees cluster outside, so as to cover one end and side two inches deep with bees, and if it had a movable bottom board he could raise one side, the east side is his choice where they face the south; by giving them ventilation they will at once go to work in racks, upper stories, or wherever he wishes them to.

W. S. Pierson has experimented with several different hives, has bought American and improved Langstroths; has tried the latter 2 seasons and cannot say he likes it, and never will make any more; he likes a hive best similar to Mr. Roop's.

Mrs. B. Chapman inquires how to prevent moths from getting into hives? That they got in her black colonies. Answered by Mr. Robertson, that moths would not trouble Italians and if they were kept strong they would drive them out. Mrs. Chapman keeps but few bees and uses a deep frame and likes it, only lost a few bees a year ago last winter, and wintered on deep frames.

C. S. Wolcott likes a medium frame similar to Mr. Doolittle's.

Mr. C. Case favors deep frames; wintered successfully in 1880-1 in deep frames.

Mr. Goodno likes deep short frames, and wants the entrance in the end of the hive, with frames crosswise, and thinks them more convenient to close up weak colonies in the spring with division boards, and with frames crosswise of the hive, each acts as a division for the wind and cold that comes in at the entrance, while, with a long frame, running lengthwise, any cold that goes in at the entrance will go through to the back end.

Mr. Robertson has no weak colonies in the spring, he draws from the strong ones and keeps them all strong; any queen who cannot keep her colony from dwindling in spring is not worth a cent.

Mr. Goodno has a queen which has done well this season, that was doubled up a year ago last spring. Six weak ones put into the 7th and this is the original queen that was in the 7th hive, and after they were doubled a week or ten days they were no stronger than the original colony.

Mrs. Sanders has had similar experience with queens that allowed their colonies to dwindle in the spring and afterward proved to be prolific. She has both square and long frames, and likes the square frames best; still, this year, she has had the best results from the Langstroth frame; but they were her best bees. She has wintered bees in both, and has no choice.

The frames used by the members present are as follows. It was agreed to let the results be shown, another year.

	Size of Frame.	No. of Col.
George W. Stanton, Sheridan,.....	11x12	51
Mrs. A. M. Sanders, ".....	11x12	50
Miss F. A. Bellamy, Ionia,.....	Lang.	30
B. Chapman, South Boston,.....	"	18
Henry Jones, Chesaning,.....	"	31
I. A. Balch, Lyons,.....	square	28
Orren Martin, Carson City,.....	Lang.	42
O. R. Goodno, ".....	10x10	65
".....	10x10	46
Day Spaulding, Pewamo,.....	Lang.	16

Norton Wrightman, Sheridan,.....	11x12	5
W. S. Pierson, Bureka,.....	11x14	70
G. M. Barney, Carson City,.....	10x10	66
Jacob Beesey, Ionia,.....	Lang.	29
B. Osborn, St. Johns,.....	11x12	40
Henry A. Rogers, Orange,.....	Lang.	13

Do not know how many of each, or how many in all. Mr. J. H. Robertson has, and at a later date, Dec. 6th, the secretary has still been unable to obtain the above information from Mr. Robertson.

Seven hundred colonies were represented at the convention; of which 186 were in Langstroth hives and 514 in square or deep frames. Under the circumstances that there was such a variety of frames represented by the members present, no frame could be unanimously adopted by this convention.

Wednesday, Oct. 11, 1882, 10 a. m., the convention was called to order. President Roop still being absent, and Vice President Stanton being called away, Vice President J. H. Robertson took the chair. The hour having arrived at which the election of officers was to be taken up, it was resolved to elect by acclamation. George W.

Stanton, of Sheridan, was elected president for the ensuing year. The following Vice Presidents were nominated and elected. 1st Vice President, Francito A. Palmer, of McBride; 2nd, L. S. Benham, Alma; 3rd, C. S. Wolcott, St. Johns; 4th, Frank Gleason, Lyons; 5th, Miss F. A. Bellamy, Ionia. It was resolved that the office of secretary and treasurer be embodied in one. O. R. Goodno, of Carson City, was elected secretary and treasurer for the ensuing year.

The convention waived the order of discussion and listened to an interesting speech from a Mr. James H. Eaton, of Bluffton, Allen Co., Ohio, who had come some miles out of his way to attend the convention and could stay but a short time. He gave us some very interesting ideas upon foul brood, and that the use of rock salt was a good, if not an effectual, remedy for the same; to be given to the bees where they could have free access to it, and that rock salt was better than any other, being more pure, and when used no bees were effected by foul brood. We all regretted his short stay as much more might have been learned from him.

"Prospects of Bee-Keeping" was the next subject taken up. Mr. Robertson said that we had encouraging prospects for the future; our honey was being sought for, and purchasers come to us to buy, while in the past we had to find our market ourselves; honey was being used by many families who had not heretofore used it, and he advocated extracted honey to be put up in 50 or 100 lb. kegs, and that his orders are increasing for that sort of package; he had no honey on hand, so great was the demand for such packages. He had realized \$10.50 for 100 lb. packages, and \$8.50 for 50 lb. packages.

W. S. Pierson said that at these meetings was the place to learn how to put up our honey and how to market it, and all should labor to drive out the cheap honey and all try to get honey up in better shape, whether it be extracted or comb. He has been engaged in the business several years and tries to produce good honey and has been able to sell his extracted at 15 cts.; he thinks we ought to make it a point to place honey, implements, and every thing used in our business, on exhibition at conventions, that we may compare, note, and profit thereby. Let each one bring the plants of his section that produce honey.

O. R. Goodno had found new and desirable market for his extracted honey to be used in the manufacture of tobacco, and, if it proved successful, would be used to a great extent in the place of glycerine which cost the manufacturer of tobacco 28 cts. per lb., while the honey, at, say 10 cts., which would be much more profitable, as it retains its weight while being manufactured, and being double or treble its cost after being placed in the goods, cannot help being more profitable to the consumers of the tobacco. Also inquiries are being made for extracted honey to sweeten grape wine, and, if it produces the flavor anticipated, they will be able to use all the honey

that Michigan can produce. He thinks that in the near future, extracted honey will be what all will try to produce, and that the prospects never were better for bee-keepers than at present.

The subject of "Wintering" was then taken up. Mr. Robertson, anticipating a severe, cold winter, advocates cutting down or doubling up and make all colonies strong. He winters in the cellar and looks after the bees every day during winter, and has water in cellar all the while, and all his bees have to winter on is June or July honey; but little or no fall honey.

Mr. Goodno gave his method of chaff packing, but should try wintering both in and out of doors. He thought bees, as a general thing, were in good condition for wintering; all preparation for wintering ought to have been made by this, though his had not been prepared as yet.

As several of the members were soon obliged to leave on the train to reach home on the same day, and desiring to know where the next convention would be held, it was voted that the next convention be held at Sheridan, Montcalm Co., Mich., on the second Tuesday and Wednesday of October, 1883.

Further, on preparing bees for winter. Mr. Goodno does not like to have bees disturbed after this date.

Mr. C. Case gave his method, and said his bees were already prepared for winter; he puts them in cellar early, and crowds the combs so closely that the honey cannot granulate, owing to the warmth of the bees.

Mr. Pierson had some bees already prepared in chaff for winter. No one doubted but what all bees should be prepared early for winter.

"Best Method of Securing a Large Crop of Honey, Weather Permitting." Mr. N. S. Pierson had been rearing bees many years and had invested in several patent hives, but all have been too complicated, and worthless. Since the invention of the extractor some have tried to extract all the honey the bees made, and it has given the extractor a bad name. The extractor is all right in its place, but do not rob the bees; give them a plenty, and, before extracting, let the bees cap at least two-thirds of the comb. He had 43 colonies this spring, and ran 8 of them for extracted honey and got 657 lbs.; found 2 upper stories with brood in them, and made colonies of them. He obtained in all 2,000 lbs. of honey.

Others spoke upon the subject but nothing practical was brought out. The convention took a recess for dinner.

At 1 p. m. the convention was called to order by Vice Pres. J. H. Robertson, Pres. Roop not having appeared. L. S. Benham, of Alma, Mich., sent in his report for the year, with regrets that he could not attend, which was as follows: Spring count 28, increase 43, queens reared 75, honey extracted 1,800 lbs., honey in comb 200 lbs.

Mrs. A. M. Sanders, of Sheridan, Mich., reported as follows: I had 50 colonies in the spring and sold one, leaving 49 for the summer's work; I increased to 80 and obtained 3,000 lbs.

of comb honey, mostly white, and 500 lbs. extracted. I worked my bees on Mr. Doolittle's plan of spreading the brood and stimulating with uncapped honey in the spring. It was very late in the season before I could safely disturb the brood combs, but when raspberries were in bloom, the hives were crowded with brood and bees and they went immediately into the crates. We had no basswood and at no time during this season has there been a flow of honey, but they got enough from clover to keep them at work in the crates until the buckwheat bloomed; the fall run lasted about 10 days. Mrs. Sanders has invented a bee-feeder which met with favor by all present. It is hoped that she will put it in use and give us further reports.

Mr. Goodno reported that he had 25 colonies in the yard in spring, increased by early nuclei 13; natural swarms 1; bought 16 colonies in August, set up 5 nuclei on Sept. 16, for experiment, other parties added 2 colonies, late in fall, to the yard, so there are 62 hives with bees in under my care, and have secured 2,000 lbs. of honey, really from the 25 colonies in the spring.

Mr. Robertson gave his plan of working bees in upper stories, by taking 2 cards from the lower story and placing in the second story, filling the lower with foundation, and then extracting from upper story. He strongly advocated extracting, instead of comb honey, which is demonstrated by the fact that he has not secured a single crate of comb honey this season.

G. M. Barney reported his success, starting with 34 colonies in the spring and increased to 66; had many more swarms but put them back; he could have had 100 colonies had he not put the swarms back; had secured 30 crates of comb honey, which would average 30 lbs. each and 2 bbls. of extracted honey.

The question drawer was then opened. The first question was "The Best Method of Rearing Queens," asked by some one who was not present at the time Mr. Robertson gave his plan. As there might be others present who did not hear his explanation, he gave it again, which was appreciated by all present.

Second question: "What Will be the best Method of Marketing our Surplus Honey in Future?" was replied to by Mr. Goodno by referring to the openings lately found and by exhausting our home market first, which is yearly increasing.

Third question: "Wintering Bees by Burying in the Ground." Replied to by Mr. Robertson, who had much experience in that way, and considered it more expensive than by preparing a cellar, and not so safe a plan.

The hour having nearly arrived at which it was necessary to adjourn, the secretary was requested to make a note of such articles as were placed on exhibition, which consisted of a smoker from Scovell & Anderson, of Columbus, Kas., one each of 3 sizes of T. F. Bingham's smokers, and a fine collection of honey-producing plants exhibited by J. H. Robertson and Isaac A. Balch, including a fair specimen of the noted Simson honey plant, and

it was resolved that each member of this society, at the next meeting, bring something in the way of bee-keepers' supplies, honey, honey-plants, wax or fixtures, to place on exhibition.

The convention was liberally attended, there being from 25 to 60 persons present at all its sessions, and our roll gives upward of 20 active members.

Before adjournment it was unanimously resolved, that this convention tender its thanks to Mr. and Mrs. J. H. Robertson, Mr. and Mrs. Isaac A. Balch and others, for their generous hospitality.

Resolved, That the thanks of this convention be extended to Mr. J. H. Robertson for the use of the hall for this meeting.

Adjourned to meet at Sheridan, Montcalm Co., Mich., on the second Tuesday and Wednesday of October, 1883.

O. R. GOODNO, Sec.

For the American Bee Journal.

Prevention of After-Swarms.

R. DART.

To prevent my bees from casting but one swarm each during the season, has caused me to try about everything recommended in this line of bee-keeping. You advised me, Mr. Editor, last summer, to change hives, giving the old colony a new stand, leaving the new one on the old stand. Out of 19 changed in this way, 4 cast second swarms; the next 10 that swarmed I served in this way: I moved the old colony a few feet from the stand and placed a new hive on the old stand, ran in my swarm, from the swarm-catcher, then drew my frames from the old swarm, shaking them in front of the new hive, thereby getting all the young bees that could not fly out with the swarm, leaving only bees enough in the old colony (say one pint) to protect the brood; set the old hive off on a new stand. Out of ten served in this way, not one cast a second swarm, but became strong and did fine work in the sections.

I do not stop to clip queen-cells, when the first queen is hatched; in 8 days there is not bees enough to send off a second swarm, the other cells are destroyed, and the swarming is over.

You may say this is too much work, but it is only a few minutes' work, and if your other work is driving you, put the old hive to one side and shake out the young bees any time of the day, or next day; it keeps all of the colonies strong and does not reduce them with after swarming, when the young brood is all hatched out.

Another experiment I have tried, with perfect success in this line, is, if you wish no further increase of colonies, when you are shaking out the young bees in front of the new colony, shake them all out, cut out all of the queen-cells, put on the sections, and have the next swarm in it, and keep on in this way.

I am using the Bailey swarm-catcher. It is quickly placed in position, in front of the hive, at the starting out of the swarm; and in a very

few minutes the swarm is all in, ready for hiving. By using the catcher, you can keep your bees from acting cross, through the swarming season. No trees to climb and no limbs to cut off. A swarm-catcher saves more than one-half of the work, if you let bees swarm naturally. We are expected to give our bees care and attention through the swarming season and honey harvest. If we do not, we get but little or nothing in return.

Ripon, Wis., Jan. 5, 1883.

Scott Co., Iowa, Convention.

The Davenport Democrat of January 7th contains the following notice of the meeting:

The largest meeting of bee-keepers ever known in this county, was held at the Court House yesterday afternoon. It occurred in pursuance of a small meeting held a fortnight since. Thirty-two persons who are interested in the production of honey as a business were present when the meeting was called to order. After some discussion, it was decided to organize a Society forthwith and elect permanent officers, which the meeting proceeded to do, as follows: President, I. V. McCagg; Vice President, George L. Gast; Secretary, J. J. Nagel; Treasurer, Israel Hall; Executive Committee, Enoch Mead, Ed. R. Wright and Philip Earhart.

A letter from B. F. Little, of Fayette county, was read. In it the writer gave his summer experience with bees, and then strongly urged that the association be organized so as to cover Eastern Iowa, and that meetings be held in different places for the convenience and benefit of members. This letter brought up the question as to whether the society should be a local one or a district one; and at last it was decided to make its jurisdiction local, christen it the Scott County Bee-keepers' Association, and fix the initiation fee at fifty cents per member. Then the roll of membership was signed by the following named apiarists: I. V. McCagg, Israel Hall, J. J. Nagel, E. R. Wright, John Madden, Enoch Mead, P. Earhart, Geo. L. Gast, Emil Magnus, H. O. Stacy, Wm. Goos, Wm. Gromoll, C. Rock, John D. Fish, Fred T. Fish, Phil. Osborne, R. J. Osborne, N. C. Wilson, Wm. Rigg, John L. Cameron, C. L. Newberry, C. M. Emeis, Joseph W. Churchill, M. A. Collins.

Twenty-four members is a goodly number for a beginning, especially as about every section of the county is represented in the muster-roll. An experience meeting was then in order.

Mr. Phil Osborne made a statement concerning the apiary of Osborne Brothers, at Le Claire. The spring count was 73 colonies, which produced 5,000 pounds of comb honey and 800 pounds of extracted honey. The bees increased to 140 colonies. They winter one-half in the cellar, and the rest on the summer stands, protecting them a little with straw.

Mr. Earhart had 15 colonies in the spring of 1882, and has 40 now. He secured 1,600 pounds of honey.

Mr. J. J. Nagel had 90 colonies last spring, and has 165 now; and the yield of honey has reached 10,000 pounds; half of which is sold and half is on hand, but there is demand for all.

The question was here raised upon the keeping qualities of honey, Mr. Gast and Mr. McCagg both stating honey did not spoil on their hands, but was good from one to three years, which covered their experience, after taking from the hives, or when first gathered.

Mr. E. R. Wright had 70 colonies in spring and 183 in the fall, with a crop of 6,430 pounds of comb honey, in two-pound sections. He favored natural swarming, and winters his bees altogether on summer stands.

Mr. C. M. Emeis stated that he had 41 colonies in the spring, which yielded 1,605 pounds of comb honey. He favored the black bees over the Italian bees.

The secretary was requested to correspond with Mr. Newman, the editor of the BEE JOURNAL, Chicago, for a lecture to be delivered at the next meeting of the association.

The meeting adjourned to Wednesday, February 21st, for a *two days' session*, the object being an exchange of views and getting hold of the best methods of bee culture.

Connecticut Farmer.

Popular Interest in Bee-Keeping.

H. L. JEFFREY.

The interest in bee-keeping is in a growing condition. The meeting of the Connecticut State Board of Agriculture has given by its helping hand an influence to the efforts of the bee-keeping fraternity that is not only an encouragement to try to spread practical information on apiculture, but the movement has inspired hesitating bee-keepers with confidence that the present method adopted by the practical apiarist is not to be classed among the patent humbugs of the many patent hives and impracticable appliances of most of the past thirty years.

The inquiries of the many waking up bee-keepers present plainly showed that the earnest taking up of apicultural pursuits would soon supply the local market with one of the richest and most healthful delicacies of vegetable production. Not only as a delicacy is honey considered in many places but it is used nearly as freely as butter. This one fact shows that before long it may be considered in our own State as much an object of industry and equally as profitable as either the growing of small fruits or any other article of food not considered to be a staple article like flour, meat or potatoes.

Many will doubtless say, I do not believe it. But look at this fact. In 1881 two and one-half tons of honey (not guess work, but actual weight) were produced in a part of Litchfield and Fairfield counties, where in 1880 there was not 250 pounds—that is a marketable article. The yield was more the past season than 1881, and

to-day not a pound is left on hand and the demand is yet unsupplied in those localities and in every place I know of the demand is greater than the supply, and as the supply increases the demand also increases in a perceptibly greater degree than the increase.

If those keeping bees do not want to have apiculturists from abroad run in their product and thereby shut out the local producer, if the watchword is to be Nutmegs first, then we Nutmegs must grate out a greater supply than has been grated in the last fifty years. Just let's hear you go to grating immediately and *get all ready* for an early spring beginning.

Woodbury, Conn.

Western Michigan Convention.

The Western Michigan Bee-Keepers' Association met at Supervisors' Hall, Grand Rapids, Nov. 29, 1882, at 1:30 p. m. President W. H. Walker in the chair.

The secretary being absent, L. S. Benham read the minutes of the last meeting, which were approved.

The election of officers for the ensuing year resulted as follows:

President, W. H. Walker, Berlin; Vice Presidents, J. J. Dodge, of Ottawa; T. M. Cobb, of Kent; Silas Remington, of Ionia; George C. Younge, of Muskegon; Treasurer, Mrs. F. S. Covey, of Coopersville; Secretary, F. S. Covey, Coopersville.

On motion of Willson Millard, the meeting discussed the subject of wintering bees, with the view of determining the best methods, out-of-doors or cellars.

Then followed a discussion on the different honey plants; perforated zinc as a division-board, and the width of sections; nearly all agreeing that $1\frac{3}{4}$ inches would be wide enough where separators are not used.

The discussions on the different subjects were interesting and instructive, but as many could not attend the following day, on account of Thanksgiving, on motion of the secretary, F. M. Cobb was elected delegate to the State convention, and the Association adjourned to meet at the same place in the last week in April, 1883.

F. S. COVEY, Sec.

Coopersville, Mich.

For the American Bee Journal.

Comb or Extracted Honey.

J. L. STRONG.

This is a question that has interested me for a number of years past, and, although my experience differs somewhat from that of most of my fellow bee-keepers, as to the relative amount of comb and extracted honey produced, never having been able to obtain twice as much extracted as comb honey in a season.

In the season of 1878 I obtained 175 lbs. of extracted honey from one colony, and 98 lbs. of comb from another. The comb honey was sold at 20 cents per lb. and the extracted at 10 cents, making a difference of \$6.65 in favor

of the extracted honey. The bees had to build their combs in both instances, that being before I used comb foundation, simply using starters of natural comb.

But, with the free use of foundation during the past season, the result has been different. This season I have taken, from one of my best colonies, 199 lbs. of comb honey, and from another colony, worked for extracted honey, I have taken 152 lbs. of extracted and 25 lbs. of comb honey. This, at the present retail price, 20 cents for comb and 15 cents for extracted honey, would make a difference of \$12 in favor of the production of comb honey.

Now, admitting the cost of each to be the same, which I think to be about right, when we offset the extra labor of extracting with the cost of sections to hold the comb honey, this is hardly a fair example of the relative amount, for the colony that produced the comb honey was located on the river bottom, with groves of natural trees all around them, covered with honey dew, while the one that produced the extracted honey were located in the town and had to work on white clover or fly over half a mile to reach the timber.

There is one thing that I have noticed, to my great delight, and that is the greatly increasing demand for extracted honey in my home market. I think that the day is not far distant when extracted honey, in its purity, will be a staple article and command as good a price in our home markets as comb honey. To this end all apiarists should labor, and use their utmost influence; for it is so much more desirable to handle, in every way, and is much better for the consumer.

Clarinda, Iowa, Jan. 4, 1883.

For the American Bee Journal.

Introducing Queens, Honey Crop, etc.

J. M. A. MILLER.

On the 1st of May last, I had 22 good colonies of Italian bees. In May and June they hardly held their own; on the 1st of July they commenced swarming, and, on the 20th of August I had sold two swarms, retained 8, several had gone to parts unknown, and I had, then, on hand, 56 good colonies.

On July 6, a swarm came out about 9 o'clock a. m. and settled on an apple tree while I was busy getting ready for harvest; at 10, they left; was gone till 12:15 m., when they returned and went into the parent hive. A few days later a swarm came out about noon and settled on an apple tree. While I was preparing a hive (as my supply was now exhausted), they went off. Next day, about the same time, they returned and went into the parent hive. I do not know whether this is an uncommon occurrence or not.

I bought of L. J. Diehl, of Butler, Ind., six dollar queens, which came in good condition. All did well and produced a nice lot of well-marked bees. One queen came about the 10th of July, and was introduced the same

day. On August 15 she came off with a large swarm, that filled the hive full.

As there is much said about caging queens, I will state my plan for doing it; first, prepare a phial of some kind of essence, say, peppermint, and odorizer on hand. I take the frames, all or nearly all, out of the hive; or enough to find the queen, dispatch her, odorize all remaining in the hive, if any; and as you place the frames with the accompanying bees, back in the hive, spray them with the odorizer thoroughly, until all are returned to the hive, then spray the queen in like manner, and let her crawl down from the top, among the bees; shut up the hive and put it on the stand, and the job is done. I have never lost one in this way.

My crop of honey this season, from 22 colonies, spring count, is 2,500 lbs.; all comb honey, and all but about 200 pounds in one-pound sections.

I find I can secure fully one-third more honey from a colony facing the north than if facing the south; I find, also, that it makes a great difference what kind of a hive I use. With the Acme hive (my own invention) I can secure at least three times the amount of surplus that I can in the American hive. My hive is two stories, brood-nest below, surplus directly on the top, fitting the lower story nicely, and holding 36 one-pound sections. I have taken as high as 150 one-pound sections of honey from a colony that was a swarm hived as late as June 10 of the same year. Although I am partial to the Italian bee, I am sure the hive has more to do with the amount of honey received, than the kind of bees used, especially if faced to the north.

I winter my bees in the cellar only, and seldom lose any; I give no upward ventilation, all open below, as in the summer. I keep the room as dark as possible, and never disturb them after putting them away in November until the last of March or first of April, as the forwardness of the season may be.

Galva, Ill.

Prairie Farmer.

A Few Practical Suggestions.

MRS. L. HARRISON.

It is well at the close of the year, to review the past, and investigate the causes that led to success or failure of a project. Before undertaking a new venture, a person should be well posted in theory, and better yet, have some practical knowledge of its routine. In conversing lately with a young man who had been engaged several years in the cattle business in the far West, he remarked, "I have paid so dearly for the knowledge I have gained, that I want now to return, and engage in it again, and profit by what I have learned."

A lady once said to the writer, "I have spent \$600 during the past summer in the bee business, and have had no returns, and all I have to show for

it, is hives filled with foundations, a queen and a handful of bees, and they will all be dead before flowers bloom." This lady had read "Blessed Bees," a charming novelette, and became infatuated with the business, and was wiser in her own conceit, than old veterans, the recipients of many stings, while engaged in a hotly contested battle with infuriated bees. In Webster's spelling-book of our school-days, we used to read "experience keeps a dear school, but fools will not learn in any other."

The hand should be educated as well as the head, and practical lessons should be given in bee-culture, at all the agricultural colleges, as is now done in Michigan. Girls as well as boys, should be the recipients of instruction in bee-culture, poultry, dairy work, and also in the care of green-houses, and raising small fruits. Let them choose the one they prefer, and then be taught it theoretically and practically, in all its bearings. Girls educated thus, will develop into independent, self-reliant women, and will never shiver in a city's garret, if misfortunes overtake them.

How often do we meet women, fashionably educated, who cannot earn enough to keep soul and body together. They can play on the piano, embroider, paint china, etc., but cannot produce what is in demand in the world's market. Luxuries are enjoyed by the few, while all seek to obtain necessary comforts, such as honey, butter and small fruits, etc. We were at a church fair lately, and looked over the articles for sale, hoping to find something that we needed, but discovered nothing but an iron holder—all fancy, fancy. "All is vanity, saith the preacher." There was plenty of darned lace, and a few mittens, but the backs of them and wrists, were all open work, and would be of little use on a cold day.

One zero day last week, we met on the sidewalk a lady and a little girl, who was a foundling left at her door some five years ago. The lady said, "this child is not old enough to go to school, and I want to give her a chance, so I am taking her to the dancing academy to learn to appear well, for it is all in appearance now-a-days you know."

Peoria, Ill.

Convention Notices.

The annual meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held in Temperance Hall, Freeport, Stephenson county, Ill., on January 16 and 17, 1883.

JONATHAN STEWART, Sec.
Rock City, Ill.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883.

C. T. LEONARD, Sec.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

The following committees have been appointed, and the programme arranged for the next meeting, by the executive committee; viz: on Resolutions; Apiarian Supplies and Exhibits; Subjects for Discussion; and Arrangements, to receive and entertain those in attendance from abroad.

Programme.—President's Address. Subject—State and National Conventions.

Subjects for general discussion:

Essays.—The "Coming Bee," W. H. Andrews. Honey plants, Native Horsemints, different varieties, Wm. R. Howard. "Extracted vs. Comb Honey," W. K. Marshall, D. D. "Bee-Moth," W. H. Andrews. "The Queen Bee, her nature and habits, Wm. R. Howard. "The different races of bees in America; their relative value to apiculture," W. K. Marshall, D. D.

Other essays are promised, and a general good time is anticipated. Ample arrangements are made to accommodate those from a distance. Those wishing to place anything on exhibition or correspond with the committee of arrangements, will be promptly attended to, by addressing, W. H. Andrews, President, McKinney, Collin Co., Texas. All other correspondence to the Secretary. We would be pleased to have any one propound questions of interest for discussion, as we have found great interest, as well as valuable information gained by the discussion of questions contributed to our "Question Box."

Wm. R. HOWARD, Sec.

Kingston, Texas.

The annual meeting of the Mahoning Valley Bee-Keepers' Association will be held at Berlin Center, Mahoning Co., O., in the Town Hall on Friday and Saturday the 19th and 20th of January, 1883. All bee-keepers are invited to attend and send essays, papers, implements, or any thing of interest to the fraternity. A full attendance is requested of all who are interested. In fact, the meetings will be so interesting that you cannot afford to miss them. We expect a lecturer from abroad on the evening of the 19th.

L. CARSON, Pres.

The annual meeting of the Champlain Valley Bee-Keepers' Association will be held at Middleburg, Vt., on Thursday, January 18, 1883, at 10 a. m.

T. BROOKINS, Sec.

The Southeastern Michigan Bee-Keepers' Association will hold their annual meeting in the courthouse at Ann Arbor, Jan. 20, 1883. All are invited. H. D. CUTTING, Pres.

G. J. PEASE, Sec., Ann Arbor.

Articles for publication must be written on a separate piece of paper from items of business.

SELECTIONS FROM OUR LETTER BOX

Bees Buried in the Snow.

My bees had a nice flight on November 20, after I had them snugly packed in prairie hay, and they went into winter quarters with an abundance of stores, and, for the past three weeks, they have been under a big snow drift; nearly the entire 11 colonies are covered out of sight. I have adopted the plan of Mrs. Harrison, of Peoria, Ill., and am letting them remain entirely quiet until the warm rays of the spring sun shall call them out. I did not work for honey last season so much as I did for increase of bees, so I only took off a small amount of honey, but as I have mentioned once before I had 11 good healthy colonies ready for winter quarters, from 1, commencing one year ago last August. Our winter, so far, has been very pleasant and favorable for bees, and we hope to see the little fellows come through all right.

W. W. EASTMAN.

Yankton, Dakota, Jan. 6, 1883.

Bees Winter Better than Other Stock.

I commenced last spring with 50 colonies; increased to 90, and obtained 3,000 lbs. of honey, one-half extracted. I might have obtained one-third more, could the bees have had full attention. I use the premium section box. After reading James Heddon's article, I think, from my experience, he is nearly right. I find by cutting the premium section box down to 4x5½x1½ inches, outside measure, I can use my honey racks without much loss in changing them. My bees seem to be wintering well. I have thus far lost but few in wintering, say about 3 per cent. since I have been keeping bees. I winter them in the barn cellar; have about as much ventilation as I would give a calf or pig, to make them comfortable. I have everything stripped from the brood chamber but the blanket, and pile them up 5 feet deep; in fact, if I could winter my other stock as safely and cheaply as the bees, I would do much better.

Jos. Wood.

Anamosa, Iowa, Jan. 9, 1883.

He Lived with His Bees.

I put into winter quarters 33 colonies; one queen proved to be a worthless drone layer. I lost 2 queens, which gave me 2 queenless and weak colonies, and 20 in fair condition. The season was uncommonly wet and cold up to June 28, at which time "the silver lining of the clouds" made themselves visible, and, at that time, I had the blues in earnest, but when the season had ended and I could count 48 colonies, and over 4,000 lbs. of honey, of which three-fifths at least was comb in 2-lb. sections, I could say from experimental knowledge that honey (especially in large quantities) is good for the blues. I did not get anything like all that could have been taken, for money matters were very close with me, in one sense, but

not in the other; I could not quite reach it, therefore my bees were idle, considerable of the time, and then it cost me considerable of honey to ascertain that my drones were not of that kind that actively participated in the building of comb and the sealing up of honey. For my success the past season I want to extend both hands to Mr. Doolittle, for I attribute much of it to his series of articles, which I followed as closely as I could, and the balance to a hard season's work; in fact, as some one has remarked, "I lived with my bees," and I could add that I can do that better than most men, for I have no one else to live with, but, for the fear that it would be taken as an advertisement, I will omit it. I have three objections to the BEE JOURNAL: 1st, it does not come often enough; 2d, there is not enough of it, when it does come; and 3d, when I get it, I have to stop everything else until I have read it.

E. F. CASSELL.

Illinois City, Ill., Jan. 9, 1883.

Poor Locality for Bees.

I am located in a very poor section of country for bees. My surplus honey in the comb was 390 lbs., extracted, 110 lbs. The beeswax I have not weighed. I had 10 colonies in the spring, and 29 this fall. Several colonies are short of stores.

B. H. WESTLAKE.

Sycamore, Ill., Jan. 10, 1883.

The Past Season's Returns.

Statement of past season's returns from my 116 colonies, spring count: Increase 24, mostly by dividing, and obtained on an average, spring count, 30 lbs. per colony. I have 138 colonies now nicely tucked up in chaff, for their long winter nap.

J. M. FRANCE.

Auburn Corners, Pa., Jan. 4, 1883.

From a Lady Bee-Keeper.

From 43 colonies, spring count, we took 4,100 lbs. of honey, about one-half comb honey in 1 and 2-pound sections, and increased to 84, mostly by natural swarming. They are in good condition for wintering. We winter in the cellar and have good success; it is dry and well ventilated. The flow of honey was great, and the amount would have been far greater could they have been run for extracted honey. A great deal is said about tin and wood separators for surplus honey. I use starters and have the hive set right and have none for them.

S. L. VAIL.

Coal Creek, Iowa, Jan. 7, 1883.

A Good Market for Honey.

I have taken, this poor season, over 3,000 lbs. from less than 30 colonies of bees. I retail at the following prices: White clover comb, in 2-lb. sections, glassed, 25 cts. per lb.; raspberry and golden rod, same; buckwheat, 20 cts. Extracted, of all kinds, 20 cents. I get the sections back again, free of cost. They are kept so clean that they can be used again another season. Honey is very scarce in the city of Troy. I think I may safely say that there is not 500 lbs. outside of my

honey in the city. It is very cold here, 5 degrees below zero to-day. My bees, 85 colonies, are in winter quarters, insured for \$550 against fire.

Troy, N. Y.

G. H. ADAMS.

Amateur's Report.

I am an amateur in bee-keeping. I had 2 good colonies last spring; increased to 5, and obtained 200 lbs. of extracted honey. I sold all I had to spare at 18 cents per lb. I think this is doing well.

R. CRAWFORD.

Patterson, N. J., Jan. 6, 1883.

Value of Good Comb Foundation.

In the spring of 1882 I had 5 colonies of Italian bees and obtained from them 25 swarms and about 820 lbs. of surplus honey, all in sections. This gives me 30 good colonies, all in good condition, for winter and spring; every hive being well supplied with honey, bees, and bee-bread. The above result being obtained by supplying every swarm with combs, saved from colonies that I lost in former years, and the above was what convinced me more than anything else, of the value of good comb foundation.

C. F. NEUBERT.

Bryant, Iowa, Jan. 6, 1883.

Are Bees Taxable?

Please answer the following questions through the BEE JOURNAL.—1. Are bees taxable property? 2. Do assessors generally assess bees? Last year mine were assessed, while those in other townships were not.

D. M. DIERDORFF.

Waterloo, Iowa, Jan. 10, 1883.

[If bees are property of value, there can be no doubt of their being taxable property. However, quite a number of assessors omit them, and hence they are not uniformly taxed.—ED.]

An Average of 100 lbs. per Colony.

The year just closed has been favorable to the bee-keepers here. The honey crop has been good, making an average yield of 100 lbs. of extracted honey to the colony in my apiary. The early part of the season of 1882 was very disastrous on account of rains and cold weather in May; many colonies of bees starved and there was an almost total destruction of the brood. But soon after, sweet clover came into bloom, and this, with the honey dews, again gave the bees a start, and they were in good condition when the fall bloom came on and gathered honey rapidly. Bees went into winter quarters in good condition.

LEE ENRICK.

Harrisville, Mo., Jan. 10, 1883.

How to use Small Sections.

In reading the various opinions about the best way to get half-pound sections of honey, the thought came into my mind, why not have the comb built in a large frame and capped over? Then, cut into pieces the right size and shape to exactly fill the section, put them in a frame or case and give them to a good colony of bees to

clean up and make fast to the section. This would be no more work than to put the foundation into the sections, and all nice combs of honey could be used up in this way. If I have any sections made for one-half pound, they must be $4\frac{1}{4}$ one way so they can be put into the same clamp on hives, and the same crate for market—with pound sections. This will save any extra fixtures. The extra amount of labor to get the half-pound section will absorb a large share of the extra receipts. Yours for progressive bee-keeping,
L. C. WHITING.
East Saginaw, Mich., Jan. 11, 1883.

Which Race of Bees?

I send you a bee in this letter and would like you to state in the BEE JOURNAL to which race it belongs. I bought a colony last spring from a farmer in a box hive; they are all about this size, some a little thicker. But I do not think they are very good, for they have not obtained any surplus honey since I had them.

ED. LASALLE.

Champaign, Ill., Jan. 11, 1883.

[The bee was all mashed up and it is difficult to say, yet it looks very much like one of the large brown bees of the South.—ED.]

Colorado and Bee-Keeping.

I clip the following from Pomeroy's *Democrat*, issued at Denver, Col., Jan. 6, 1883: "The second annual meeting of the Colorado State Bee-Keepers' Association will convene in the rooms of the Horticultural Society, next Saturday, for the purpose of electing officers and the transaction of other important business pertinent to the occasion." Colorado, the youngest commonwealth in the American Union, the centennial State, proudly boasts of her wealth in minerals, yet has leisure to cultivate bees. The flora of her mountains and canyons must be utilized, as well as her deep, hidden treasures.

Mrs. L. HARRISON.

Peoria, Ill.

My "Bee Business" in 1882.

In April, 1882, I had 61 colonies and by inserting empty combs in center of the hives every few days, I succeeded in getting all colonies very strong by May 1st. But the most precious queen of all in the world to me (my wife) was taken sick at that time, so, of course, the bees were neglected. Many colonies had limited supplies, and, when I stopped feeding and caring for them, they dwindled rapidly. One colony starved to death. My wife died on May 21st, and for a few days after that I still paid no attention to the bees, so, in reality, my bee season began June 1st, with 60 colonies in only ordinary condition. They were not so strong on the last day of May as they were on the last day of April. From June 1st I gave my whole time to the bees and as they had no "gap" in their business, I had no holidays till frost came. I had a great many swarms but "doubled up" persistently

all through the season. I hived as many as 6 swarms that clustered together all in one hive, or rather in 3 hives tiered up. By doubling, and tiering up for room, I only increased from 60 to 130. I obtained 2,773 lbs. of comb honey, and 7,402 lbs. of extracted honey, making a total of 10,175 lbs. I only used 30 lbs. of comb foundation and paid \$18 for hired help.

C. W. MCKOWN.

Gilson, Ill., Jan. 8, 1883.

Frames across the Entrance.

MR. EDITOR:—Please give me your views, through the BEE JOURNAL, on the plan of placing frames crosswise of a hive instead of lengthwise? Where can we obtain half-pound sections? I have my bees packed on a summer stand, in sawdust, and, so far, they are doing splendidly. I see some objection to the Syrian bees on account of their restless disposition. I have one colony of Syrians and I find them quieter than any others. Days that other bees will fly, they remain perfectly quiet.

E. W. THURSTON.

Hagerstown, Ind., Dec. 29, 1882.

[The half-pound sections can be obtained of the dealers in apiarian supplies. Within a few weeks you will find many of such, advertised in the BEE JOURNAL.

Some like to have the frames across the entrance, but nearly all bee-keepers prefer the ends to come to the entrance. It is more convenient for the bees coming home loaded to get to the desired place of deposit. It, however, is quite an unimportant matter, and, but for the sake of uniformity, might be subject to the notion of the apiarist.—ED.]

A Swarm Filled its Hive in 9 Days.

I had 6 colonies in 1881; bought 4; and lost 1 by queenlessness in March. They have increased to 29. Several gave 3 swarms each, and one gave 4 swarms. A swarm that came out on July 18, filled its hive in 9 days. I obtained from them 500 lbs. of honey besides the increase.

D. WATTERSON.

Roscoe, Ill., Jan. 8, 1883.

The Use of Separators.

Seeing that there is a diversity of opinion in regard to the use of separators, in obtaining comb honey, I will give what little experience I have had in trying to obtain comb honey in marketable shape, without the use of separators. In 1881, I tried two hives without the use of separators. One of them has twenty-four sections filled full of foundation. I got four boxes that could be glassed, the rest of them were either bulged or the comb built into each other so badly that the sections could not be separated without breaking the honey badly. Of the other hive, 27 sections, only 8 could be glassed and fit to be put on the market. In the season of 1882 I had no

better success than the year before, so I do not want any more box honey without using separators. I have always used tin separators until the last season. In the spring of 1882 I bought a very nice lot of wooden separators of C. VanEaton, and I believe they are a great improvement. They make the entrances to the boxes larger and the bees enter the boxes more readily, and being wood they are warmer than tin, and the bees will cluster in the sections in cool weather a good deal quicker than they will where metal is used. Such has been my experience during the past season. I shall give them a more thorough trial next season, and shall use the wood separators almost exclusively. L. DUNSMORE.
Livonia, N. Y., Jan. 9, 1883.

Feeding in Winter.

Last fall I bought a colony of bees in a bee hive; they did not have much honey and I commenced to feed them. Cold weather came on soon after, and I put them in the cellar; the thermometer standing about 40°. I put some honey over them in the hive, but they do not move around, and their honey is almost gone. Now, how will it do to put them in a warm room?

A SUBSCRIBER.

Nashua, N. H., Jan. 9, 1883.

[It might do to put the colony in a room just above the freezing temperature, and feed the bees with some hot syrup made of coffee A sugar. This they will store in convenient cells for use, as they need it.—ED.]

Another Step Higher.

In reply to that article in the BEE JOURNAL on "Another Advance Step," to prepare young men who desire to become scientific apiarists. For a young man to do this, he should work in the apiary at least three years, in order to qualify himself in all the branches and be able to handle any apiary. I was an apprentice 3 years and have made several mistakes that have cost me from \$300 to \$500 each, besides coming very near discouraging me in bee culture. If a man wants to qualify in the business he should work under some of the best talent in the country for awhile, and, after that, they should continue to practice and study. Practice is better than all the book learning a man can get. I would not take an apprentice for less than three years, and a man that cannot spend that time should not handle bees at all. It has taken me six years to get where I am, and I consider that I am in advance of my instructor, Mr. J. W. Lindley, who had a large apiary when I commenced and my means were limited. I have 112 colonies of bees in good condition. I advise all to commence business right and they will then know what they are doing.

CHAS. FOLLETT.

Osage, Iowa, Jan. 7, 1882.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES for 1883.

20 cents per line of space, each insertion,

For either the Weekly or Monthly Editions.

A line of this type will contain about 8 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

SPECIAL RATES.—Advertisements will be inserted in both Weekly and Monthly editions, at the following prices, if wholly paid in advance:

SPACE.	One month	Two months	Three months	Six months	One Year.

For the Weekly alone, 20 per cent. less than the above rates. On yearly advertisements, payments may be made quarterly, but must be in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Attention is called to our new and liberal advertising rates for 1883.

Local Convention Directory.

1883. *Time and Place of Meeting.*
 Jan. 16,—N. W. Ill. and S. W. Wis. at Freeport, J. Stewart, Sec.
 18, Champlain Valley, at Middleburg, Vt. T. Brooks, Sec.
 19, 20.—Mahoning Valley, at Berlin Centre, O. L. Carson, Pres.
 20,—S. W. Mich., at Ann Arbor, G. J. Pease, Sec., Ann Arbor.

 Dec. 5-6, Michigan State, at Flint. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Subscription Credits.—After sending subscriptions to this office, we would respectfully ask every one to look at the label on the wrapper of the next two papers, and there they will find the credit indicated thus: Those who have paid for the first six months of this year will find "June 83" after their names. Those who have paid for the whole year will find "Dec. 83" on their papers. The credit runs to the end of the month indicated.

The credit given on THAT LABEL is a sufficient notification of subscriptions due and receipt for payments made. If not so indicated within two weeks after sending money to us, you may be sure something is wrong, and should write to us about it. It will save annoyance and trouble if our subscribers will give this matter due attention.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

James Vick.—From the appearance of *Vick's Floral Guide*, which is on our desk, we should judge that the young Vicks are "chips of the old block," as the *Floral Guide* with its lithographed cover is handsome enough for the parlor table. It is printed on the best of paper, has three colored plates of flowers and vegetables, and full of useful information. Those who send 10 cents for it cannot be disappointed, as the plates alone are worth the amount. Address, as in past years, JAMES VICK, Rochester, N. Y.

CLUBBING LIST.

We supply the *American Bee Journal* and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

Publishers' Price. Club

The Weekly Bee Journal,	\$2 00..
and Gleanings in Bee-Culture (A. I. Root) 3 00..	2 75
Bee-Keepers' Magazine (A. J. King) 3 25	3 00
Bee-Keepers' Exchange (Honk & Peet) 3 00..	2 75
Bee-Keepers' Guide (A. G. Hill).....	2 50.. 2 35
Kansas Bee-Keeper.....	2 60.. 2 40
The 6 above-named papers.....	6 35.. 5 50

The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth) 3 25..	2 75
Bees and Honey, (T. G. Newman) " 2 75..	2 50
Binder for Weekly Bee Journal.....	2 75.. 2 50
Apiary Register for 100 colonies	3 50.. 3 00
Apiary Register for 200 colonies	4 00.. 3 50

The **Monthly Bee Journal** and any of the above, \$1 less than the figures in the last column.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The time for the usual winter rush of correspondence is here, and we wish to impress upon all our patrons the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but should be written on separate pieces of paper.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., January 15, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The supply of extracted honey is fully up to the demand. My quotations are: 7c. for dark and 9c. for light, delivered here.

BEESWAX—It is quite scarce. I am paying 27c. for good yellow wax, on arrival; dark and off colors, 17@22c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand is good for extracted in barrels as well as in glass jars and tin buckets; arrivals are fair. The demand is fair for comb honey, which, however, is not cheap enough to make trade lively. Extracted brings 7@10c. on arrival; comb honey, 14@20c.

BEESWAX—Is scarce and brings 20@27c. on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—January month, and still there is a large surplus of comb honey on the market. Prices are weak owing to large offerings, and anxiety on the part of shippers and holders here to realize on the product. Extracted honey is steady, but the demand is light.

We quote: white comb honey, 1@12 lb. sections, 17@18c. Dark comb honey, hardly any demand. It is held at 12@14c. Extracted—White brings from 9@10c.; dark, 8@9c.; kegs, half-barrels and casks bring about same price.

BEESWAX—Yellow, 30@32c.; dark, 27@28c. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Business in this line has been extremely dull the past week. Quotations are little more than nominal.

White comb, 17@20c.; dark to good, 11@13½c.; extracted, choice to extra white, 9½@9½c.; dark and candied, 7@8c.

BEESWAX—We quote 25@28c.

STEAKINS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull. Comb, at 16c. for large or hard to 19c@20c. for choice bright in small packages; extracted at 8@9c.; strained, 6½@7c.; choice, in smaller quantities, brings more.

BEESWAX—Prime bright steady at 27@28c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Has changed in price a very little, we find it necessary to sell all grades about 1 cent per lb. less. Best white, in 1 lb. sections, 20@21c. per pound; in 2 lb. sections, 19@20c. Extracted is very dull indeed, hardly any sale.

BEESWAX—Scarce, 28@30c.

A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—There is only a moderate supply of choice to fancy white clover honey, and prices are still held firmly, though the demand is not large. Buckwheat and extracted honey continue slow.

We quote: White clover, first quality, 1 lb. boxes, 25c.; 2 lb. boxes, 23@25c.; buckwheat, 1 lb. boxes, 20c.; 2 lb. boxes, 16c. Extracted, white, 11@12c.; dark, 8@9c.

BEESWAX—The supply has been light and prime lots held a shade higher.

Western pure, 30@31c.; southern, pure, 31@32c. D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—30c.

CROCKER & BLAKE, 57 Chatbam Street.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Attention is called to a few changes in our clubbing list for 1883, as given on this page. Those interested will please take notice.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

SWEET CLOVER SEED.—New and clean, 25 cts. per lb. BEN CLENDENON, Grinnell, Iowa.

DUNHAM COMB FOUNDATION—40c. per pound; extra thin and bright, 10 sq. ft. to the lb., 48c. Send for samples. Wax worked 10c. per lb. F. W. HOLMES, Coopersville, Mich. 13w1y

Bees for Sale.

50 Colonies of Bees, in Gallup frames, cheap.
200 Colonies of Bees, in Langstroth frames in prime condition.

J. H. ROBERTSON,

36wtf

Pewamo, Ionia Co., Mich.

STUDENTS IN BEE-CULTURE.

Having had such good success for two years past in teaching the theory and practice of honey-producing, I have now made arrangements to accommodate a large class during the coming season. I shall aim to give a five months' instruction, at the end of which time I hope and expect to turn out bee-keepers competent to profitably engage in the pursuit, or such as will be sought for as assistants, at wages above common laborers. All interested, write for terms.

BEE-KEEPERS' SUPPLIES

on hand, as usual. Beeswax wanted.

JAMES HEDDON,

Dowagiac, Mich.

1*tf

LIVE BEE-KEEPERS WANTED,

to introduce the new lime cushion, the only protection yet discovered that will carry the bees safely through winter and spring without fail. Send \$3, for right to retail this cushion in your county, or send \$5 for complete right to patentee. Remit by registered letter or P. O. order.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the
State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST*.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Fur.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is truly up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, M. D.*

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS*, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *code* medium of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the *Weekly Bee Journal*.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide for Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping. by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture. by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book. by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey. or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur. by Thomas G. Newman, in GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Bzierzon Theory.—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey as Food and Medicine. by Thomas G. Newman.—This pamphlet describes in the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market. including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Foul Brood; its origin, development and cure. By Albert R. Kohnke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity. by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. Price 5 cents.

Bees in Winter. with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. Price 5c.

Queen-Rearing. by Henry Alley.—A full and detailed account of TWENTY-THREE years' experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price \$1.00.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35c. postpaid.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Moore's Universal Assistant, and Complete Mechanic. contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metals and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postpaid, \$2.50.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. Ask your bookseller for it. Sent post-paid for 40 cents.

Chicken Cholera. by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Deutsche Buecher, Ueber Bienenzucht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen. von Thos. G. Newman. Dieses Pamphlet enthält Velehrungen über folgende Gegenstände—
—Derlichkeit des Bienenstandes—
—Honig pflanzen—Erziehung der Königin—
—Zütern—Schwärmen—Uteger—
—Verfegen—Italienisieren—Zücker von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin.—von Thomas G. Newman. Dieses enthält eine klare Darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigkuchen, Formkucheln, Puddings, Schaumkonfekt, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Consumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten.—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniss der verschiedenen Pferdekrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Rezepte. Preis 25 Cents.

THOMAS C. NEWMAN.

925 West Madison Street, Chicago, Ill.

MEDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood 3 strings, 7 1-3 Octaves, full patent cantant, graceful, our new patent overstrung scale, beautiful carved legs and lyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which in any way tend to the perfection of the instrument, has been added.

127 Our price for this instrument, boxed and delivered on board cars at New York, with fine Piano Cover, Stool, \$245.

Reduced from our late wholesale factory price, \$295, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Pianos, \$160 up. Over 15,000 in use, and not one dissatisfied purchaser. Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years.

SHEET MUSIC 1/2 price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

MEDELSSOHN PIANO CO.,

21st St. N. Y. Box 2558, New York.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Chondodon Bonedelli*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no uncharitably noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are unquestionable and its curative character absolute, as the writer can personally testify, both from experience and observation. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Only Imported by HAYLOCK & JENNEY, (Late HAYLOCK & Co.)

Bee and Honey Show in Michigan.

Nothing will give more prominence to honey, and aid in its popular consumption than large and attractive exhibitions of it at fairs, and we are glad to know that Michigan is taking the lead in this matter. It is a pattern well worth the copying, and the result will, no doubt, surprise even its most active workers. We have received the following letter from Prof. Cook, with the list of premiums to be awarded at the next Michigan State Fair:

DEAR MR. NEWMAN:—I send the following, as I know that you and others will not only be interested but rejoice in our success. We owe our secretary, H. D. Cutting, as also the Agricultural Committee, a hearty vote of thanks. You see we increase \$64.50 on last year's premiums.

There is a bright outlook in this direction. Improved bees, better pasturage, and grand exhibitions at fairs, promise much for apiculture. We are to have a nice building and the right to make sales.

If Michigan does not have a grand exhibition next fall, then I misjudge her apiarists.

A. J. COOK.
Lansing, Mich., Jan. 16, 1882.

The full list of premiums, both of last year and this, are given below, so that all may see what has been accomplished by Mr. Cutting and Prof. Cook, in their labors with the Board of the Michigan State Agricultural Society.

DIVISION II—BEES, HONEY, ETC.

Superintendent—W. J. BAXTER, Jonesville.

COMPETITION OPEN TO THE WORLD.

All entries in this division must be made on or before Tuesday, the second day of the Fair, at 2 o'clock, p. m.

II—CLASS 34.—BEES, HONEY AND APIARIAN IMPLEMENTS.

1882. 1883.

For 1882.....115 00

Increase for 1883.....\$64 50

The Hon. Louis Wallbridge, one of the principal apiarists of Canada, has been appointed Chief Justice of Manitoba, and has gone there to enter upon his duties. The Judge is a thoroughly practical and progressive apiarist.

Origin of Noise in Swarming-time.

Much has been said and written about the object of making a great noise, by the ringing of bells, beating of tin pans, etc., when a swarm issues from the hive, and is in the air. In the BEE JOURNAL for January 3, Mr. Arthur Todd, of Philadelphia, Pa., (formerly of Algeria, Africa,) referred to the matter, as being no proof that bees could hear, and that it had no influence on the bees to make them settle. His letter was as follows:

On page 503, of the BEE JOURNAL for Dec., 1882, reference is made to certain remarks of Sir John Lubbock, and the influencing of bees, when swarming, to settle by making loud noises, etc., etc. I am decidedly of the opinion that it is not to the sense of hearing on the part of the bees, that the custom of beating tin cans, etc., took its rise, but to the sense of hearing in the human family, and why? For the simple reason that the ancient laws relating to bees, vested the ownership in a swarm only to him from whose grounds they departed, provided he followed them, and kept them in sight until they alighted. Now, what more natural than to "kick up a row" for the sole purpose of letting others know that the bees seen in flight were being followed. I regret that I cannot at present consult my library of bee books and give the words of the ancient laws. I think the wording would go far to prove my hypothesis correct. ARTHUR TODD.

Philadelphia, Pa., Dec. 25, 1882.

Mr. Todd is evidently correct, and is corroborated by a correspondent in the London *Journal of Horticulture*, who says that "the custom of ringing bells, beating pots or kettles, and otherwise making as much noise and hubbub as possible when a swarm issues, was in vogue in very early ages. Since we do not believe that the noise has any effect whatever in causing the swarm to settle, we can only suppose that the institution of the custom was for the purpose of giving notice to the neighboring bee-keepers that the operator on the bell, drum, or kettle claimed the rising swarm and identified it as his own.

"Habit is second nature," says the proverb, and the habit in question holds sway over the rural bee-keeping world, for long centuries after the cause for and establishment of that habit has been forgotten. By an old law, of the time of Alfred the Great, a bee-keeper is permitted to follow and to secure his swarm if on another's property; but he must keep the swarm in sight, and that his neighbors may know he is following it he must ring a bell as he pursues it.

The bell-ringing is now oftener replaced by yelling and the beating of a kettle or rattling of fire-irons, and the bee-keeper is not so much intent on calling his neighbors' attention to the fact that he is following his bees, as on charming the swarm and causing it to alight, seduced or terror-stricken by his rough music.

The law of Alfred evidently explains the origin of the custom, although, as we said above, the habit prevailed centuries before that law was made. Virgil refers to the tin-can music in his fourth Georgic. Plato, Pliny, Varro, and Columella all speak of it, and attribute the settling of the bees either to fear or joy; while Aristotle is not certain what the effect is which the beating of brazen vessels has on the bees.

A violent concussion of the air often affects a swarm; hence some fire a gun near the hovering swarm to cause it to settle; others throw gravel or dirt among them. Many bee-keepers use a Whitman's Fountain Pump to bring the bees down; this disorganizes them, causes general confusion, and they usually settle at once. The wetting of their wings also makes them in a hurry to obtain shelter, the same as they would in a shower of rain.

These are modern practical ways of doing what has been, by the superstitious in ages past, sought to be accomplished by charms, such as bell-ringing, pan-beating, and such like noisy demonstrations.

The *Indiana Farmer* says that "the two most important questions to the bee-keeping interest of the country are providing pasturage for the bees, and as to the size of the packages for surplus honey." These questions are now being discussed in the BEE JOURNAL, and while it is the duty of every bee-keeper to find "pasturage for the bees," just as much as for other stock, no progressive apiarist will fail to give the "best package for surplus honey" the due amount of thought, and by many experiments and repeated trials, the right size and shape will be developed in due time.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75.

Attention is called to our new and liberal advertising rates for 1883.

A Sweet Endowment.—The following item is from a local paper sent us by Mr. E. Pickup, of Limerick, Ill.:

Last spring was very poor for bees; so Edmund Pickup fed about 50c. worth, per hive, in bee candy, sugar and honey. In the fall he got a little over 4,000 lbs. of comb honey; an average of 138 lbs., spring count, and increased from 29 colonies to 90, besides 6 "swarms" otherwise used, and 8 got away. More than one-half were black bees. The best colony in spring produced 236 $\frac{3}{4}$ lbs., and 3 swarms; the best old colony 99 $\frac{1}{2}$ lbs., beside one swarm. From the best colony 122 $\frac{3}{4}$ lbs.; from the 2nd best, 65 lbs.; from the 3d best, 27 lbs.; the 4th best, 29 $\frac{1}{2}$ lbs. Honey at 15 cts. per lb., and new colonies at \$5 each, gave a net compensation of \$30.50 per hive in spring. John, brother of Edmund, has an interest in the bees; so the Pickup brothers show great skill and industry in bee-keeping. Yesterday Mr. Edmund Pickup gave to the Limerick church 666 $\frac{2}{3}$ lbs. of honey—\$100 worth—for an endowment fund. This is a praiseworthy act of Mr. Pickup, and will live after him.

By a copy of the Savannah, Ga., *Abend Zeitung*, we notice that Prof. Reclam gave a lecture on "Honey as Food and Medicine," in that city lately, in which he drew largely upon our pamphlet on that subject, strongly endorsing it and advising a more generous use of honey in families for food, and highly recommending it for its medicinal qualities; and for healing wounds he says its value cannot be over-estimated.

The next meeting of the Maine Bee-Keepers' Association will be held at Dexter, February 8th and 9th, 1883. A large attendance of bee-keepers from different parts of the State is expected, and it is hoped that it may be one of the most interesting meetings ever held by the Association. A large exhibit of hives and implements, used in the apiary, is expected; and all attending the meeting are earnestly requested to bring something to help make a good display. Any article sent to the Secretary will be placed on exhibition, and cared for, free of charge. The following is an imperfect outline of the programme for the two days: First day:—Secretary's report; Treasurer's report; reports of Vice Presidents of the different counties represented; President's address; choosing committee to award preferences on articles exhibited; reading of essays and discussions. Second day:—Election of officers; report of committee on articles exhibited; reading of essays and discussions. Essays are expected on the following subjects:—Feeding Bees; How to make Bee-keeping Profitable; Artificial Pasturage; The Coming Bee, etc., etc.

Ripley, Me. WM. HOYT, Sec.

Bee and Honey Statistics in Illinois.

In accordance with the "hint" given by Mr. S. B. Atwater, on page 57 of this issue of the BEE JOURNAL, we sent a letter to C. W. Fisher, Esq., Secretary of the State Board of Agriculture, asking for any statistical information in his office on bees and honey in Illinois during the past year. In reply we received a very gentlemanly letter, and the following table, which will be found very interesting to our readers:

We are sorry the table is not quite complete, and would suggest to the Board of Agriculture that they add two more columns for the coming season—one for "increase" of colonies, and a division of the honey column, giving the number of pounds each of "extracted" and "comb" honey produced. Then it will be much more valuable.

Only a Crape on The Door.—We have just received a copy of a new motto song and chorus, called "Only a Crape on the Door," composed by Edward J. Abraham, a most touching and affecting song. It is very easy, and can be played on piano or organ.

Of the many sad scenes in the city, you see,
Of the poor who are wanting for bread;
Of the homeless who wander so sadly about,
Of the mourners who watch o'er their dead.
Of all these sad scenes, the saddest of all,
Should you travel this wide world all o'er;
Just pause in your journey should you chance to
see,
Only a Crape on the Door.

CHORUS.—Only a Crape on the Door—
A friend or a loved one no more;
Just pause for awhile should you happen
to see
Only a Crape on the Door.

Price, 40 cents per copy, or three copies for \$1.00. Published by F. W. HELMICK, Music Publisher, 180 Elm St., Cincinnati, Ohio.

We have a few copies of our pamphlet entitled "*Bee Culture*" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Feeding Bees in Winter.—A correspondent in the *Germantown Telegraph* thus describes his method of feeding bees in winter:

In the first place let me say that I would prepare the feed in the shape of a syrup, thus:—Take of pure clean water two pounds to four pounds of sugar; A coffee or extra C is best. Bring the water to a boiling heat and then add the sugar; stir well until it again boils, and skim off all impurities; then let it cool and fill up glass tumblers and tie cotton cloth over each, and turn them upside down over holes in the top of the hives, if of the old-fashioned box or gum log, and you will have the satisfaction of seeing the tumblers soon emptied and stored in the brood combs. If you are using a good movable frame hive you can feed your syrup in the top of it in the following way: Take some old bits of combs and lay in the surplus chambers, and pour the syrup over them, and the bees will take it all down. Feed as fast as they empty the glasses or combs referred to. We should feed all weak colonies late in an evening, which will prevent robbing in a great degree. If you use the glass tumblers to feed from, I would recommend boxes to be turned over them so as to keep robber bees out.

Referring to the lecture by the Rev. O. Clute, of Iowa City, Iowa, on "Bee-Keeping by Modern Methods," delivered before the "Iowa State Agricultural Society," at Des Moines, last week, the *Iowa State Register* remarks as follows: "He gave an address of considerable length, going extensively into the minutiae of the fascinating subject, and having a bee-hive at his side to help elucidate his idea. When he had concluded, he was subjected to a long fusilade of questions from his interested hearers, and his ready answers proved even more instructive than his address proper. The address and subsequent discussion will be printed in the forthcoming report of the Society."

The Springfield, Mass., Weekly *Republican* gives the following notice of the BEE JOURNAL:

If there are bee-keepers in the *Republican's* constituency or those who would like intelligently to make a venture in apiculture, no more valuable source of instruction can be recommended to them than the AMERICAN BEE JOURNAL, published both weekly and monthly at Chicago by Thomas G. Newman. Mr. Newman is an enthusiast in bee-culture, and has a happy knack of drawing out all the other bee-keeping enthusiasts of the country, who contribute to his journal the fruits of their observation and experience.

How to Ventilate Chaff Hives.

G. M. DOOLITTLE.

The principal method of ventilating our hives, for the past 10 or 15 years, has been by what is known as "upward ventilation." The means generally employed has been a quilt or porous cloth placed over the frames, on the top of which was placed chaff of various kinds, cut straw and sawdust, which were to absorb the moisture from the bees, or let it pass off, and at the same time keep the bees dry and warm.

As the entrance was to be left open, to some extent, this plan gave a slow draft of air through the hive, thus keeping the air pure, and carrying off the moisture thrown off by the bees. This draft must be in proportion to the size of the colony, else the bees might be kept too cold, as too great a draft would carry away the heat generated by the cluster, so that they could not keep up the desired temperature, without consuming more honey than was best for their existence, in order to maintain the proper temperature; or, if too little, the moisture would not be carried off.

To get this draft just right, appears to be a very nice point, if we can judge from the many losses in the past. My bees have been prepared as above described, for the past 8 years, and my losses have been large in severe winters, while in mild ones but little difficulty has been experienced. To try and arrive at the proper amount of air which should pass through a hive, I have experimented largely, and believe that I have erred in allowing too great a draft through the hive.

As all our material used is so porous, a very small entrance allows the warm air generated by the bees to pass off very rapidly, and more especially so, when the cluster does not come in contact with any of the surrounding material, only at perhaps two or three places. Thus the heat passes into empty space, and is carried through the porous material much too fast.

From past experience, I believe, if we shut our hives as tightly at the bottom as we conveniently can, that enough air will get in through the cracks to furnish all that is needed for safe wintering.

I am trying, the present season, another plan of ventilating, which, so far, bids fair to excel our old plan of "upward ventilation." It will be remembered that Mr. A. G. Hill, editor of the *Bee-Keepers' Guide*, has always favored chaff packing, but has opposed upward ventilation. He simply places sawdust around the outside of his hives, and lets in all the ventilation the bees get, at the entrance.

After studying upon the matter for a while, I concluded to try a few of

my colonies on a plan similar to Mr. Hill's, and pack the majority as I had formerly done.

In accordance with this determination, I prepared a few colonies thus: I took the enameled cloth and cut it large enough, so that it would completely cover the tops of the hives and tuck down over the sides and also where the side boxes were, placing the enameled side next to the bees. I then put in the packing, filling the sides as full as possible, and also the cap or chamber to the hive, making it so full that I was obliged to place hooks on the same, and hook it down to the body of the hive, in order to keep it in place.

After thus preparing them, I opened the entrance the full size, in all the hives, which is $\frac{3}{8}$ inches high by 14 inches in length. As an experiment, I raised four from the bottom board, placing an inch block in the entrance, which gives them air from the whole width of the front of the hive, an inch in depth. Although this last allows the snow to blow in, to some extent, the bees seem to be in splendid condition.

We have just had some very cold weather, the mercury going as low as 15° below zero, yet, upon examination, I find but little frost in the hives, and that in the extreme outside corners, the farthest away from the bees. In one or two I found ice formed in drops, as large as the end of my finger, upon the enameled cloth at the edges of the hive, but the bees invariably look small, bright and healthy; while some of them with upward ventilation show distended abdomens, with here and there a spot of excrement on the combs.

So far, our winter has been a steady cold one, and if it does not warm up enough so that bees which are on their summer stands can have a flight before the 1st of March, I fear we shall hear of mortality amongst our pets again.

Under the most favorable conditions bees can stand from 4 to 6 months of confinement, without harm, but where we are lacking, seems to be in not knowing just what these "most favorable" conditions are. If from long confinement and the large consumption of honey necessary to keep up the desired temperature, the bees find their vitality giving out, instinct seems to teach them to go to rearing brood, to supply the place of those about to die. As the young bees from this brood are not capable of standing the cold, to that extent which the old bees have been capable of, when the majority of the old bees perish, the colony soon dwindles away.

That the consumption of pollen has anything to do with this state of affairs, is not sufficiently proved to warrant us in excluding it from the hives. The point I am desirous of arriving at is, how can we best secure a condition in which to place our bees, so that an undue consumption of honey can be avoided during a long confinement. I think chaff packing, together with lower ventilation, may give us some light on the subject.

Borodino, N. Y., Jan. 15, 1883.

The Half-Pound Honey Section.

DR. G. L. TINKER.

DEAR EDITOR:—A sample dove-tailed half-pound section, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{8}$, as suggested by Mr. Bingham in a recent issue of the *BEE JOURNAL*, is at hand from Mr. A. E. Manum. It is too thin to look well, and, even if there should be no trouble to get the bees to build straight combs in it without separators, it would not have the advantages of some other form.

A half-pound section may be made to put immediately upon the brood frames, if it be of a thickness equal to the distance from centre to centre of the frames. Or a rack of sections, of the right thickness, could be put upon the frames, so that the passage ways between them and the sections would be continuous. This would be of great advantage in many respects, and might fully compensate the extra cost of so many small sections.

For several years I have sought some plan to put a case or rack of sections down at once on the brood frames, so that the passage ways would be continuous, and found it could not be done with a two-inch section; but the half-pound section can be made just the thing for this purpose, and since some change in the surplus arrangement of most bee-keepers will be necessary to accommodate a half-pound section, less than 2 inches in thickness, it would be far better to adopt the most advantageous size and form of section at once, and then make the surplus arrangement to fit, than to undertake to make the half-pound section to fit a surplus arrangement made expressly for sections of other sizes.

First, then, the sides of the half-pound section should be $1\frac{3}{8}$ inches wide; the top and bottom pieces $1\frac{1}{8}$; and it should be used without separators, to make it pay. The thickness being given, the proper dimensions would be $3\frac{1}{4} \times 3\frac{3}{4} \times 1\frac{3}{8}$.

This size would be a little gem indeed, and, beyond question, could be used without separators, if any sized section could be; 36 of them could be put upon one rack (9 rows and 4 in a row), which could be tiered up 4 sections high to advantage, and thus give room for 72 lbs. of honey. In arranging a lot of small sections upon a rack, it will be seen at once that the square form can be worked to the best advantage.

The rack may be made of slats $1\frac{1}{8} \times 1\frac{1}{8} \times 17$ inches long, nailed at the ends to inch pieces. The brood frames would need to be on a level with the top of the body of the hive, which should be flat and have a removable case and cover. The hive, being flat on the top, will permit the sliding of the rack endwise over the frames, so that no bees will be killed. I have tried a similar plan to this with entire success. If the rack is accurately made, the tiering up can be very expeditiously done by sliding one rack of sections over the other, endwise.

If it should be found impracticable to use any size of section without separators, then the proper dimensions for a half-pound section, according to my ideas, would be $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{8}$.
New Philadelphia, O., Jan. 1, 1883.

The Coming Bee—Enough.

JAMES HEDDON.

I will here try to make my position upon this subject so clear that this tedious controversy may waste no more time or paper, and Messrs. Demaree and Shuck may turn their time to writing upon other subjects. I here publicly invite Mr. Demaree to give us a ringing article on "How Best to Market a Large Crop of Honey."

First, I believe that we have two well-known races of honey bees in this country—Germans and Italians? Am I correct?

Second, That we have at least two distinct strains of each of these well-known races, viz., among the Germans a smaller black and larger brown bee, and, among the Italians, a shorter-bodied, bright golden-colored, and longer-bodied, darker, leather-colored bee. Am I right?

Third, That, of the German strains, the larger brown bee is vastly the superior one. Of the Italian, the long, darker bee is the best. Am I right?

Fourth, That each one of these races possess traits much superior to the other, traits much desired by the more extensive producers. Is this an error?

Fifth, That when all the characteristics of both races are considered carefully, the Italian aggregates the most, and is, all points considered, the best bee extant; this is admitted by the majority. Anything wrong about this?

Sixth, That any, and all of these points of excellence are hereditary. Are they not?

Now, as it is a fact, to say the most, the Germans are only *slightly* inferior to the Italians in the *aggregate*, and that in the vital points of rapid, white and straight comb building, non-swarming and quick and white finishing of sections of comb honey, they are their *superiors*. I, 5 years ago, decided to breed from all of the good and bad qualities of both races, rather than both good and bad of either one alone, all the time discouraging the bad, and encouraging the good, by all the processes known to breeders, the same as any wise breeder would do with either race in its purity. Have Messrs. Shuck or Demaree shown us why I could have developed more good qualities (such as white, straight and rapid comb building) by breeding alone from a race that did not possess it? But we do not see through the same glasses.

I am looking forward to the near day when I shall have from \$5,000 to \$10,000 worth of bright comb honey in nice white little sections to sell—all the product of one season.

Do you know that, do what I might with these bright golden Italians, I

could never accomplish it, unless with double the number of colonies that I expect to use?

Mr. Demaree always talks to us about "thorough-bred stock." His mind always runs horse and cornward before he has properly canvassed the subject of breeding the best qualities in bees.

"Oh! Mr. Demaree, come back.
From your blue-grass, corn pasture,
And look at this theme
As should a bee master."—C. J. R.

Why tell me, over and over, that I "can never establish a fixed race with only two pure races?" Who said I could? I never knew whether I could or not; I only knew that I could get more surplus honey with less friction and stings, with these crosses, than with either race pure; as I have them transiently "fixed," and that it will pay me much the best, even if I have to fix them all the time. I am of the opinion that had I any pure strains of any race of bees known, that I should "fix" them as long as I kept them. The report that tells of my saying that the light Italians are better-natured than the dark ones, is an error, for I did not, and I have always maintained that the dark ones are the best behaved bees of any pure race, and that the crosses between these and the brown bees are equally as well behaved. I am sorry you should have come out at the sight of a shadow, when the same time and space might have been devoted to "How to Market a Large Crop of Honey."

I think it was Mr. Demaree that told us that the Italians were hybrids themselves. Well, if they are, being composed (as they must be *a la D.*) of "several races," there may be a chance for me to "get there" yet. Mr. Shuck accounted the impoverished, honeyless condition of his bees, at one time of year, to the season, and then a result, with *any* bees, proved a honey shower, and credited the latter result all to the stock. His first statement disproved the last, and the last proved too much, or nothing. Did it not?

Mr. Demaree tells us that crosses sport so much that they are liable to fall back to worthlessness (if they do not fall below the worth of the brown German strain I started with, I will stand it, well), because they are not (like the pure races) "fixed," yet Mr. Shuck proposes to breed up his coming bee out of this *fixedness*. I will leave Messrs. Demaree and Shuck to settle this between themselves.

In the tenth paragraph of Mr. Shuck's reply to me, he says that my "theory (it is really my practice) looks well on paper, but in practice it presents quite a different picture;" and then, to prove it, cites us to his failure with a *pure* queen, imported from Italy, selected at that, during the years 1880-81.

Several have written me to ask if I should reply to Mr. Shuck. Mr. Snyder, of Clarksville, writes me: "Shuck is right after you; I think you will have to give up your coming hybrid bee," and, in the next line, he says: "I am quite a poultry breeder, and I

am producing a cross between two distinct pure breeds, which I think much superior to either pure race, and I could give good reasons for my coming fowls?" Mr. Demaree will please correct Mr. Snyder. Had he not better add a blue jay or red fowl to his crosses?

Well, the reason I had not replied to Mr. Shuck was because I could see no argument to reply to. When his article came, I was entertaining an old queen and bee breeder and honey-producer (second to none in America, in my opinion), and we read the article together and neither of us could see what I was going to "hit at," and it lames my muscles to strike into the air and hit nothing.

But, really, is it not a matter of demonstration? Must we not let the utility of the bees by all who use them, decide the matter? I fancy I hear an accord from Messrs. Hutchinson, Oatman, Miller, and a whole host of men, who are known to "get there" early and often, saying, with our worthy editor, "the coming bee will have the right number of yellow bands, be it one or many?"

I may be too grossly practical, but I feel something like the practical old lady, who, after doing her full share of amassing a fortune from the dairy, henry and farm, took her big, awkward son "Eli" to the fair, to run to a 20 rod post and get off the \$5 gold piece first. When on his race, and nearly been led by numerous competitors, the old lady, who stood by in breathless suspense, cried out, "do not jump so high, but GET THERE, ELI."

Please excuse me if I put more confidence in the opinion of bee-keepers who *get there* than in those who do the *high jumping*. The ink of imagination has no affinity for the ear of experience.

Dowagiac, Mich., Jan. 5, 1883.

For the American Bee Journal.

Wood Separators for Surplus Honey.

C. R. ISHAM.

MR. EDITOR:—By to-day's mail I send you a few *wood separators*, the same as we have used in our apiary during the past season, and of standard thickness, one-sixteenth of an inch. I put one or two into the package, which have been in use, that you may the better judge as to their practicability for the purpose of securing straight combs with smooth, even surface.

In an article published in your JOURNAL a short time ago, Mr. F. C. Benedict gives the experience of himself and neighbors who have used wood separators, more or less, for several seasons past, all of whom are among our most experienced and successful honey-producers, and follow bee-keeping for profit more than pleasure.

Mr. Benedict's article on "Half-Pound Sections," marks him as a writer possessed of good judgment and who knows what he is talking about.

He has had experience with wood separators and half-pound sections, and those contemplating a change in their surplus arrangements to conform to what just now seems to be a "popular idea," may do well to pause and consider awhile, before making the proposed general alteration.

I will here remark (although we have high authority to the contrary) that for us to think of dispensing with separators for surplus honey would be like going back to old box hives, minus brimstoning the bees.

I will now give a few brief reasons as to why I am strongly in favor of using some kind of separator for sectional boxes.

First. When wood is used, the bees do not travel as much over the honey, preferring to cling to the separator, especially when the nights are cool and honey is coming in slowly; consequently the combs do not get so badly soiled, as when used for runways or to cluster upon.

Secondly. We can get just as much honey with, as without them, and have the sections evenly filled, giving them a much nicer and more attractive appearance, which is always appreciated by the connoisseur.

Thirdly. If we are in the habit of glassing our honey,—they are simply indispensable.

Fourthly. That those of us who like to take off the filled sections as soon as capped, and move the unfinished ones to the center of the rack, would have a troublesome job without separators between the sections, for, while some combs would rub against each other, others would be too far apart, making the whole operation a trying ordeal.

Fifthly. Upon general principles to have the combs built just as we want them, believing that straight combs are more attractive than crooked ones, whether or not we may wish to use glass—and that the cost of separators are nothing in comparison to benefits received.

We want our honey in shape to command the highest market price and give the best satisfaction to the consumer—believing that a white bass-wood section, well and evenly filled with honey, is an article of "beauty" and a "joy" to possess—better than wheat, for it can the more readily be exchanged for gold or greenbacks and at a far more remunerative price.

Peoria, Wyoming Co., N. Y.

[The samples of separators are received, and some of them look as though they had done excellent service. We do not believe that those who are producing a fancy article of comb honey can afford to dispense with the use of separators. We think they are indispensable; with very careful work some may do without them for a time, but, for producers of comb honey in general, they cannot be dispensed with,—without costing more for extra time and care, not only while sections are on the hive, but in crating for

market, than their entire cost, each season.

For many reasons wood is preferable, and when cut so nicely as are those sent by Mr. Isham, we can see no objection to their use.—ED.]

For the American Bee Journal.

Bees Removing Eggs.

O. E. COOLEY.

"Do bees remove eggs from one cell to another?" Yes; and from one comb to another, sometimes. A colony of mine lost its queen, about July 1st, and after waiting a sufficient length of time for them to have reared another, I gave them a frame of brood, containing brood in all stages, from the egg to hatching bees. I let it remain until all of the brood had been capped, at least two weeks; in fact, most of it had hatched out, but there was no queen cells built on it, and no queen in the hive.

Again I exchanged frames, putting back the frame first taken from the queenless hive, which was now again full of brood in all stages, but still the bees built no queen cells on that frame, nor on the frame next to it, on either side. I thought it useless to do anything more with them, and thought I would wait, and, perhaps, Mr. Alley would fill an order for a queen that I sent him, and paid for, over three years ago, but the queen did not come. About six weeks after giving the last frame of brood, I discovered that the hive had a queen, and was filled with brood. The bees must have moved an egg and built a queen cell in some other part of the hive, or the queen could not have been there.

Ridgeway, Iowa, Jan. 2, 1883.

For the American Bee Journal.

Our Honey Resources.

W. H. STEWART.

Some are of the opinion that 100 colonies of bees are as many as can be made profitable within a radius of five miles, while others believe that each inhabitant of the rural districts might keep 100 colonies to advantage, as far as pasture is concerned. We are not aware that any one has ever demonstrated practically, that either opinion is well founded. You cannot expect me to give my views, in full, on this question, in one short chapter, but I will just give a hint, and leave the matter for further consideration.

I hold that all animate life is governed by the same universal law, from which there is no divorce. The law that dictates that one class of beings shall live by the sweat of their brow, is just as arbitrary to every other class of living creatures.

Very much of the work of the bee is done in the night; much is done in the swamps, on the mountains, and in the forests, and even that portion of

her work that is done in our immediate presence is by us, by no means fully understood.

Her cut is so slight, her blow so light,
And given in such rapid succession,
Our nerve is so slow, 'tis but little we know,
By our most labored observation.

The two planes of life, occupied by the honey-bee and the human family are widely separated, and in the nature of things we can comprehend about as much of her plane of life as she can of ours; very little more. Yet, as both are subject to the same law, when we learn how we can obtain from the nectar-secreting plants, a portion of their choice sweets, then we have obtained a reliable key that unlocks the dark mystery that would otherwise conceal very much of the labors of the honey-bee from our vision. If we would know the resources of the honey-bee, we must first learn our own resources for obtaining wealth.

We have learned, by experience, that our stores are only born of labor, and that the measure of stores corresponds to the amount of labor that we are able to accomplish; and, further, that the better and more advantageous our surroundings are the more labor we are able to accomplish in a given time. As man is able to accomplish more under favorable conditions, even so it is with the honey-bee. If we allow them to increase their number of colonies by natural swarming, then it is highly probable that much of their time in the height of the honey season is consumed in preparing a new home in some old hollow tree. And, again, if we detain the swarm, and give them no better home than a straw basket or empty rough box, they must labor through the whole season to prepare their rude home for the coming winter. But if they are properly divided, and the new colony given a good frame hive, filled with sheets of brood-comb, or even sheets of comb foundation, they are often found able not only to prepare for winter, but to give us large yields of surplus honey. Thus we perceive that favorable conditions inside of their home is, in reality, a honey resource.

The life of the bee in the working season is only six weeks, and it has been proven during the last season, by Jerome Wiltse, Falls City, Neb., that she is *able*, and *does* gather *honey* from the field at the age of six days after hatching, if surroundings are favorable; and then she has but five weeks more that she can work.

Now, we come to a most important question, viz.: "What is the bee to work at during this five weeks?" Is she to build combs for brood and storage? Is she to stand guard at her door to protect what little she has against robbers? Is she to be tormented out of her wits, by being stifled with smoke, and having her nest all torn to pieces every day or two, by unwise bee-keepers; or will we prepare and protect her home, and let her gather honey all the remaining five weeks of her life?

I have stated that human life is a key to the life of the bee. If we were

in want of maple sugar, how would we act? We would first prepare storage and means of evaporation, and, when all was ready, we would cut the fiber or *cells* of the tree, to make it leak its sap. Then we would gather the sweet sap as it leaked from the wounded tree, evaporate the water from it, and have the desired amount of sugar.

If we desire to obtain cane sugar or syrup, when our storage and evaporating fixtures are in order, and the cane is in proper condition, we *cut* and *crush* the cane and force from it the sweet juice, evaporate the water and retain the nectar. I apprehend that some are beginning to see the point and ask if I believe that the bees must go to the forest, and cut bleeding wounds in the trees, forcing them to leak out a portion of their sap, and surrender it up to be carried away and evaporated by the bees. And, in reply, I answer yes; most assuredly do I believe it. I know of no law that would guide the maple or cane, to pour out, *unbidden*, its sweets to the bee, and at the same time withhold it from man.

If the bee would have honey, she must first have her house, workshop and storage room in order, and when any one or more of the classes of plants are in proper condition, at the proper stage of their new growth, she must find where the plant has by accident or otherwise been wounded, or find some of its most tender points and inflict the wound, as best she can, and then gather home and evaporate what leaks from the wound that is made. I hold that bees wound the bloom of clover, buckwheat, linden, and, in fact, all other plants before they are able to extract from them the desired sweet.

This being true, then all must admit that a proper condition in and about the home (or hive) of the bee is one of the greatest resources for honey. Webster's first definition of the word (*Resource*) is as follows: "Any source of aid, or support; any expedient to which a person may resort for assistance, safety, or supply."

Mr. H. M. Morris, of Rantoul, Ill., lives where there is more corn than other honey-yielding plants, and his bees store large quantities of corn honey, each year. He finds that bees work very lively at the base of every leaf, and at every joint from top to root of the stalk. The truth is, that the rind of the stalk is the most tender at those points, and the bees mutilate the rind, making the stalk bleed, and then gather the sweet fluid. Who can tell how much sap 1,000 acres of corn could spare for the honey bee? Who can tell how severe trimming white clover is able to endure, and yet bloom on and on, in newness of life and beauty? We know that it thrives best, in our stock pastures, where it is subject to the most severe pruning. Who knows but it would be acting true to its nature in yielding a hundredfold more sweet, if it were cut and scared by a hundredfold more bees? If white clover had been plenty near the bees of Mr. Morris, they would most likely have worked

on that, and have paid but little attention to the corn.

Again Webster says: "An enterprising man finds resources in his own mind." Allow me to ask horticulturists where they find their resources for choice fruits? Is it not in their own mind? You must tear the little seedling tree, root and branch, from the bosom of its dear old mother earth, and then cut off its little tender head, and wax on to its shoulders the head of a stranger, then transplant, cut off its limbs and continue to cut and scar, until you have finally forced it to present to you the delicious fruit. The resource for this fruit is in the enterprising mind!

Who can say that our resources for honey are any more hidden, or limited, when touched by the hand and genius of an enterprising people, than are our resources for the choice grains, fruits and flowers?

Then kindly treat the queen of sweet,
Give her a cozy home;
Each part complete, and keep it neat,
From bottom floor to dome.

Of pure fresh air, give her a share,
But not too hot or cold;
Adorn her home, with nicest comb,
Of the most perfect mold.

Her days are few, 'tis very true,
But keep her on the wing;
She loves to scale the floral hill,
And choicest treasures bring.

With hand and brain, do all you can,
And blend your life with hers;
Resources vast, you'll find at last,
In all the coming years.

Richland Co., Wis., Jan. 10, 1883.

The Standard Langstroth Frame.

M. M. BALDRIDGE.

The season for making hives being again at hand, it may be well to call attention once more to the proper dimensions of the Langstroth standard frame. The proper place to find the exact measurements of the standard frame is in Mr. Langstroth's work on bees, where he gives explicit directions for making his hive. I will now copy from the 3d edition of his book, page 372, what he says about the frame, to wit: "Top, $19\frac{1}{8} \times 11\frac{5}{8} \times 5-16$ in.; bottom, $17\frac{3}{8} \times 7\frac{3}{8} \times 1\frac{1}{4}$ in.; ends, each $8\frac{5}{8} \times 7\frac{3}{8} \times 1\frac{1}{2}$ in." As the bottom should be nailed to the end pieces the outside length of the standard frame, as given by Mr. Langstroth, himself, is $17\frac{3}{8}$ in., instead of $17\frac{5}{8}$ in. as given by some of his pretended followers. The space between the ends of the frames and the hive is given by Langstroth as $\frac{3}{8}$ in. This makes the hive $18\frac{1}{8}$ in. from front to rear, inside measure. The space above the frames is 5-16 in., and under them, $\frac{1}{2}$ in. The inside width of the hive for 10 frames, is $14\frac{1}{4}$ in.

It seems to me that the exact length and depth, outside measure, of the standard frame should be strictly adhered to by all parties making the same for their own use or for the public. Should this be done, the following modifications of the standard frame will do no harm, to wit: I make and prefer said frame as follows—top piece $18\frac{3}{4} \times 7\frac{3}{8} \times 5-16$ in.; bottom piece $17\frac{3}{8} \times 7\frac{3}{8} \times 1\frac{1}{4}$ in.; ends, each, $8\frac{5}{8} \times 7\frac{3}{8} \times \frac{3}{8}$ in. Ex-

perience has demonstrated that the top piece should not be more than $\frac{7}{8}$ in. wide. I find that 5-16 in. space at ends of hive, $\frac{1}{4}$ in. above the frames, and $\frac{1}{2}$ in. under them, is just about as near right as we can get it.

This requires accuracy in getting out the hive material, but when the machinery for making hives is as it should be, and properly adjusted, it is just as little work to cut out the stuff accurately, as otherwise. No bungling mechanic has any business to make hives for the public, nor for himself either. I rather mistrust that we are indebted to Mr. Bungler for sending out sample hives for others to copy from, and that this explains why there are so many $17\frac{5}{8}$ in. frames in use for standard frames.

But there must have been more than one bungler at work to explain the following extract from a letter recently received from the makers of the Given Foundation Press, to wit: "In regard to standard Langstroth frames, we have received sixty (60) different orders for them, and we find but two alike! They vary from $\frac{1}{8}$ to $\frac{1}{2}$ inch." Now this shows that the makers of hives are simply following Mr. Bungler, or else their own notions, and not any accurate formula, such as is given by Mr. Langstroth. There should henceforth be a change in this matter or else the subject and importance of a standard frame should be dropped altogether.

St. Charles, Ill.

Experiments in our Apiary.

D. VIDETO.

The past season, though conceded to be a poor one in this section, has given me very satisfactory results. The average product per colony has been about 40 lbs. and the average profit a little over \$5. Very little attention was given to the production of comb honey, as it sells little or no higher in our market than extracted, and we have never yet discovered methods by which we could so produce it as to make it profitable at any reasonable price. We have tried all the popular methods for producing comb honey, and never yet found the colony that would produce one-third as much comb honey as it would of extracted.

Since learning, through the very kindly instructions of Mr. James Heddon, how to wire frames and put foundation into them, I have been able, at least, to attain entire satisfaction on this point. It is due, perhaps, to say that I have improved somewhat upon Mr. Heddon's method, which is recommended to persons having no press. Instead of pricking the wires into the foundation, "cell by cell," I have arranged a handle to a brass clock wheel about two inches in diameter; this is run lengthwise of the wires, pressing it down into the wax. I had almost concluded that I should be compelled to purchase a foundation press, more particularly that I might work the foundation on to the wires, but after such experience have dis-

carded the necessity of a press for this purpose, as I can run off a large amount of work in a short time, and in every respect satisfactory.

Of course, there is no difficulty in finding persons who will manufacture and sell the very best samples of comb foundation, and as long as such shall be found in the market, there seems no need of a machine, unless working up wax is remunerative. I have been really delighted with my success in wiring my frames and putting on foundation.

I have also been trying some of those condemned dollar queens. It was very easy to see, on their arrival, that they were *forced*—too small and feeble looking, to insure much promise of profit. They were introduced, however, and thus far have given tolerable satisfaction. My experience has been that queens from such, during the swarming season, are all that may be desired.

We are strenuous in our praises of the Italians, and consider them much superior to the blacks in disposition and honey-gathering qualifications. The "Coming Bee" with me, thus far, has been some Italians and as many hybrids. I am disposed to agree with Mr. Heddon, that the best bee is the one that will produce the most honey. Extreme gentleness is conceded to be a characteristic of the Italians, a trait of character which I very much admire, but fear we all are sacrificing the honey-gathering qualities too much to secure it. I have no better bees than some cross hybrids.

North East, Pa., Jan. 9, 1883.

Comb Honey Surplus Arrangements.

LEROY WHITFORD.

I have taken great interest in the half-pound section movement, as manifested in the discussions of the conventions, and especially in the BEE JOURNAL. The subject has been so thoroughly ventilated that it has no doubt already taken shape, to be carried into practice in many apiaries, and yet I can but regard it as an unwarrantable extreme, and that whoever undertakes to run a large apiary for comb honey in half-pound sections will have occasion to swing back to the golden mean.

Its advocates teach that it must be adopted or rejected *in toto*, as it never will do to have two kinds of sections in an apiary. Now, while it is admitted that the demand for larger sections will continue (even for the two-pound), the idea seems to be that one must produce the one-pound package, and another the half-pound.

Dr. Miller says that if he knew that all others were adopting these two styles, he should continue to use the two-pound sections. This means that the retailer must keep in stock, honey from three different apiaries, to meet the wants of his different customers.

It strikes me, that I, as a producer of comb honey, should meet the demand with different weights, as the extracted honey-men have, with the

pails of different sizes. I am the more anxious to do this, when I remember that the half-pound buyer this year will, most likely, be the two-pound buyer next year.

I have invented—do not be frightened at the word, for it will not be patented—a case which is readily adapted to the half-pound, pound or two-pound sections, or it may be used for two or three styles in the same case, and separators are used more conveniently than on any other arrangement; and I think I know what I am talking about, having "tried all things" and found nothing good enough to "hold fast."

I dislike the broad-frame and have studied for two years to get rid of it, and still retain the separators, for I consider them indispensable. The outcome is a surplus arrangement which I have used on 20 hives during the past season, with great satisfaction, as it facilitates the manipulations very much and does away with a lot of bulky "traps," which clutter up the shop and store-room.

The improvement which gives me these advantages I will call a "section sill" made of tin. I take a strip of tin $1\frac{1}{2}$ in. wide and fold it lengthwise. Then crimp the two edges at right angles, $\frac{1}{4}$ in. each, giving it the form of the letter T (sectional view); the lower part being double and the top single. Now, take another strip 13-16 in. wide, and put it into the T-shaped piece, and settle them together solid, with a hammer, and prick the sides so that the middle piece cannot get out. The case is simply a square box without bottom, but an inch band is nailed around the bottom. For pound sections a kerf is sawed into this band $4\frac{1}{4}$ in. from the sides into which this sill is pushed. It should go tightly, and will, if a fine back saw is used; now, suppose you put in the two outer rows of sections, the outer ends will rest on the band and the inner ends on the tin sills. Now, take the tin separators, cut to the right length to reach clear across the case, and drop them in between the sections. They will rest on the upper part of the sill just right for the bees to work under and over them in the usual way. But the middle sections are not provided for. For two more tiers of sections you have only to take a strip of tin $1\frac{1}{4}$ in. wide, and bend the edges down at right angles 5-16 of an inch, and drop it into two saw kerfs at each end, $4\frac{1}{4}$ inches from the sills.

If it were desirable I could use sections in the middle $8\frac{1}{2}$ inches long, holding 2 pounds, or I can space for Heddon's 2 13-16 in. sections and these sills can be moved in a moment to accommodate one or the other. It makes no difference what thickness of section is used, the separators will fit them, if you use 2 inches or one. Of course, the tin sills rest on the frames crosswise, and the bees have the freest possible access to the supers. You would be surprised to see how easily they lift off, and how easy it is to clean the tins in the wash boiler.

I have made a long story, and yet I fear I have not made myself understood, so Mr. Editor, I will send you

a sample of those tin sills which will aid your comprehension.

Fearing that I have already made my communication too long, I will only say in closing that I shall, the coming season, offer my customers half-pound and pound sections of honey in the same case, and fitting, mixed in the same shipping crates, and test the market, but to produce all half-pounds for hotels—my principal market—I am sure would be a great mistake.

Stow, N. Y.

[The samples of "tin sills" are received, and, from the above description of their use, we have no doubt of their utility. It is a matter, however, that must be decided by those who use them. Two tin sills are sent to us; one with a rest to support the separators, and the other is a plain, cheaply-made one for the middle sills. They are placed in our Museum for the inspection of visitors.—Ed.]

For the American Bee Journal.

A Few Odds and Ends.

T. F. BINGHAM.

The report of the Northwestern Convention at Chicago, Ill., shows that 70 members were present; of whom 32 took part in the discussions.

By a careful review of the secretary's official report of the North American Bee-Keepers' Convention, there is circumstantial evidence that there were present at the meeting 18 persons. Of these, 11 took part and said something. Twenty-seven reports appear from different parties (seven of these persons' names appear as a part of the eleven as taking part in the discussions). Judge Andrews, of Texas, and Dr. Blanton, of Mississippi; in fact, all the far-off delegates do not appear in the report as having taken part in the discussions.

On page 665 of the BEE JOURNAL for Oct. 18th, is a letter giving circumstantial evidence that two others, not elsewhere reported, were present. These two added to the 18 reported by the secretary would swell the report of the North American Bee-Keepers' Convention, for 1882, to 20. The letter above referred to gives some further light, which may add to the number 4 ladies, who took the lead in a carriage, in the trip to Mt. Healthy. By a strict construction, this would add two not elsewhere reported. Thus our bee-keeping friends in England, Germany, etc., when they read the report, saw that there might have been 22 persons in convention assembled at Cincinnati, Oct. 3, 1882.

Mr. Muth must have written that letter after the best spirits (of which he speaks) had departed, or he would not have so mixed up the sexes in the "crowd," or construed what I said as reflecting on him. I merely said "That the lingering of foul brood about Cincinnati ten years, might be regarded as evidence against curing it by medication."

"Mr. Heddon as a specialist," page 18 of the BEE JOURNAL for 1883; this is liable to misconstruction. The fact of his getting such returns, as a novice, is full of encouragement for beginners, and is a concise commentary on his criticism of "Blessed Bees," in the same issue. Mr. Heddon's incongruous sentence, referring to "capacity," on page 20, of the January number, illustrated capacity for cruelty; but when he went further and gave a test by which one could decide whether he was "more experienced," etc., he illustrated more. It may be clear to him how one can write four times and not think once; if so, he may well say apiculture has progressed.

I am very glad J. C. Newman & Son gave their practical experience in half-pound sections: their size, with separators, and their sale when offered in large quantities, settles at once all theories. Goods of most kinds are sold in "lines," differing in size and quality, and if bee-keepers should follow the same plan and use such sized section as each one thought best,—the market would soon determine whether various sizes were most salable,—or whether only one—and which one.

Abronia, Mich., Jan. 15, 1883.

For the American Bee Journal.

Bee and Honey Statistics.

S. B. ATWATER.

During several months past, I have read a great deal of what has been said on the subject of collecting apian statistics, by correspondents of the bee papers, and in the reports of the discussion of the question by the various bee-keepers' conventions. I do not remember seeing anything stating that any statistics on the subject were being collected, anywhere in the Union, at State expense. For some time I have looked for some farmer in Illinois to write to the AMERICAN BEE JOURNAL and volunteer the information that the Town Assessor, last spring, not only asked him how many head of fat cattle and hogs he marketed; how many tons of hay, bushels of wheat, corn, oats, rye, apples, potatoes, etc., and how many pounds of butter and cheese he produced; but that, for the first time, he asked him something about his bees.

Can it be that all the farmers have forgotten it? It is possible; for in fact I had forgotten just what was asked. But I think only one or two questions were asked, and perhaps these are not the same the committee on statistics are now asking through the bee papers.

I send you herewith a copy of the Illinois law to be found on page 3 and 4, "Laws of Illinois, 1877," and call the attention of the committee on statistics to what is said in the second section of this act about the power of the Board of Agriculture to add to or omit questions from the blanks furnished the Assessors. If more questions are desired by the bee-keepers, no time should now be lost in bringing influences to bear in making a change as the Secretary of the State Board of

Agriculture delivers the list to the State Auditor on or before the first day of April of each year.

AN ACT to secure the Collection and Publication of Agricultural and Other Statistics. Approved and in force May 25, 1877.

SECTION 1. Be it enacted by the people of the State of Illinois, represented in the General Assembly, That it shall be the duty of the Secretary of the State Board of Agriculture to prepare and deliver to the Auditor, on or before the first day of April in each year, forms and blanks similar to those used in the assessment and return of property, one or more copies of which forms the State Auditor shall send by mail to the County Clerks of the several counties on or before the date aforesaid for their information and guidance.

SECTION 2. It shall be the duty of the County Clerk of each of the several counties to provide schedules and blanks according to the forms provided by the Auditor for the use of Assessors and Deputy Assessors in the same manner and at the same time as is or may be provided by law for the assessment of property, to cause such census schedules to be filled by all persons within their respective assessment districts in possession of property, concerning which, information is required by this act. Such schedule shall truly and distinctly set forth the number of acres he, or she, or they may have had the preceding year in fall wheat, spring wheat, corn, rye, oats, barley, buckwheat, castor beans, beans, peas, Irish potatoes, turnips, and other root crops, and the number of each produced the preceding year; the number of acres in timothy grass, and the number of tons of hay and bushels of seed produced therefrom the preceding year; the number of acres in clover, and the number of tons of hay, and bushels of seed produced therefrom the preceding year; the number of acres in cotton, and the number of pounds of lint, and the number of bushels of seed produced therefrom the preceding year; the number of acres sown in flax, the number of pounds of fibre and the bushels of seed obtained therefrom the preceding year; the number of acres planted in tobacco, and the number of pounds produced therefrom the preceding year. And the Secretary of the State Board of Agriculture shall have power, after the first year, to add to or omit from the foregoing schedule such items as the State Board of Agriculture shall designate.

SECTION 3. It shall be the duty of all persons owning or in possession of property concerning which information is required by this act, to make out and deliver to the Assessor at the time fixed for the listing of property for taxation a schedule as aforesaid, properly and correctly filled, and it shall be the duty of said Assessors or Deputy Assessors to properly fill and add up the blanks and schedules aforesaid and to return the same correctly footed up, to the County Clerk at the same time and in the same manner as is now or may be required for the return of assessments.

SECTION 4. It shall be the duty of the County Clerk to revise, correct, tabulate, and foot up the statistical returns made to him by the Assessors or Deputy Assessors of organized townships in counties under township organization, and of congressional townships in counties not under township organization, and to transmit to the State Auditor with his return of the assessment of the county, an abstract of the agricultural statistics of the county in the form required by the schedule and blanks furnished by the Auditor; and it shall be the duty of the Auditor to transfer without delay such abstracts to the Secretary of the State Board of Agriculture, who shall revise, correct, and compile the same, and publish the results in the annual report of the transactions of the State Board of Agriculture, for the year or years in which the statistics were collected.

I would further suggest to the editor of the AMERICAN BEE JOURNAL that whatever information there may have been collected by the thousands of Assessors in this State on this subject, last year, can probably be had by addressing a line to the Secretary of the State Board of Agriculture, Springfield, Illinois. If the statistics are already published, a copy, perhaps, can be obtained by addressing the member of the legislature from your district. Viola, Mercer Co., Ill., Jan. 8, 1883.

[As suggested by Mr. Atwater, we have made application for any statistics that may be in the hands of the Secretary of the State Board of Agriculture, and a Table furnished by him may be found on page 51 of this issue of the BEE JOURNAL.—ED.]

For the American Bee Journal.

Are Separators a Nuisance?

A. L. GOULD.

I send my opinion, in compliance with Mr. Caldwell's request.

The more I handle bees, the more I am convinced that they have a good deal of human nature about them; or more correctly, that they possess some qualities in common with man; and that it is much easier, in dealing with bees, as in dealing with men, to *coax* them to do well, than it is to *drive* them to do so. In compelling them to build uniform combs in small sections by the use of separators, you disregard their instincts, and they will spend much time in pouting, sometimes leaving whole sections untouched, and hang out on the outside of the hive. But coax them to do reasonably well, by putting 4 sections, side by side, with nothing between, with a starter of clean white comb in each (I have not used a scrap of foundation during the past season), and, finding room to cluster, according to their instincts, they will at once take hold of the four combs and build them down together, and finish them straight enough to pack.

We have packed 10,000 pounds of honey in the comb, this season, and much the larger part of it built without separators, and have not been obliged to lay aside half a dozen combs for the home market. Some of them were more than full, and some not quite straight; but by putting such ones next a thinner one, all went in without touching. And the inconvenience of packing is not worth naming in comparison to the bother and loss attending the use of separators. We have worried with them several years, because the authorities recommend them; but we shall do it no more. We have shaken off the nuisance and cut up the tins for other purposes.

January 11, 1883.

For the American Bee Journal.

Separators of Wood.

R. H. FINCH.

In the BEE JOURNAL of Dec. 27, page 820, is an article on wood separators. Now I claim to be the first person in this country that adopted the wood separator, which I did five years ago. The idea first suggested itself to me, by being in a factory in Geneva, Ohio, where I then lived, where they manufactured wood ribbon from a round log, rolling around, and a knife set to take off any thickness they saw fit for fancy splints, tooth picks, etc., being cut into narrow strips afterward. The thought struck me that it might be cut into strips of the right width and length, and tacked on the section frames, and answer a better purpose than tin. I also bent some 1-lb. honey boxes out of it, lapped the ends and fastened them with glue; that was when we were using dove-tailed boxes. I ordered several hundred yards of the material, cut to a thickness according to the sample I enclose to you. I also sent a sample to I. B. Haines, of Bedford, Ohio, who spoke very favorably of it in a letter to me. I have used it for separators ever since, and prefer it to tin. I never have been bothered with bees "bracing" any more than with tin, and they never run over the comb with it. The cost is not over one-fourth of that of tin, and mine has not me over one-eighth as much. I can put it on as fast as I can tin separators, by cutting it with a penknife to the size, and tacking each end with 4 small wire nails, 2 at each end. If you change it every season, it will not cost one-half as much as tin. Not being anxious to appear in print and having very little time to write I have never mentioned it before.

I have 50 colonies of bees, but I have had very little increase and very little honey during 1882; no one in this section of the State has one-half a yield, and very little increase. I have sold all my honey at home. I took the first premium at Summit county, O., agricultural fair on bees, honey and hives; what I call the improved Langstroth with improved surplus, holding 28 one-pound boxes. I find they work better than with 56 boxes, as most parties use them.

I also have an improved entrance for controlling robbers, which I consider better than anything I have ever seen; I can stop robbing in one hour in nearly every instance.

We live in hopes of a better season during the coming honey harvest. No one here has any more than paid expenses, and many not that.

Bees are having dysentery badly in this section, from honey dew. We think some have suffered quite badly; there was a profusion of honey dew late, and bees just swarmed the woods after it.

I like the old BEE JOURNAL, but I do not take much stock in those large yields published. I will give these parties \$500 in cash to instruct me how to obtain one-half that quantity and pay all expenses besides. I suspect that it was not weighed on standard scales.

Sharon Center, Ohio, Jan. 8, 1883.

For the American Bee Journal.

Western Bee-Keepers' Convention.

Upon previous notification, a goodly number of persons interested in apiculture, of Jackson and adjoining counties, met at the court house in Independence, Mo., Dec. 23, 1882, for the purpose of organizing a bee-keepers' society. A permanent organization was effected by electing J. A. Nelson, of Wyandotte, Kans., president; L. W. Baldwin, of Independence, vice-president; S. W. Salisbury, of Kansas City, secretary; and P. Baldwin, of Independence, treasurer. After some discussion, the following articles were adopted:

1. This organization shall be known as the Western Bee-Keepers' Association.

2. Its object shall be to promote the interests of bee-culture.

3. The officers of this association shall consist of a president, vice-president, secretary and treasurer, and be elected by ballot for the term of one year.

4. The president, vice-president, secretary and treasurer shall constitute an executive committee.

5. Any person may become a member of this association who shall subscribe his name to these articles and pay into the treasury the sum of one dollar. Ladies free.

6. Each meeting of this association shall be at such time and place as may be decided by a majority vote.

7. These articles may be changed or amended at any regular meeting by a two-thirds vote of the members present.

Owing to the lateness of the season the exhibits were few, although there was displayed a very fine package of honeycomb by L. W. Baldwin; also extracted honey from the apiaries of F. J. Farr and Jonathan George.

Mr. Salisbury stated that the tendency, especially in the east, was for smaller packages of comb honey, weighing not more than one half-pound, as having a ready sale at a higher price and more satisfactory for general use.

L. W. Baldwin thought that one pound packages were small enough for practice use, as the change of apparatus, etc., of the apiary for procuring honey comb in smaller sections would be accompanied with great expense. He stated that he had sold his crop of comb honey the present year, put up in 1½ pound sections, at 23 cents per pound in the Kansas City market.

There was represented at the association about 1,000 colonies of Italian bees and 26,000 pounds of honey distributed among the different members as follows:

Name.	Spring.	Fall.	Extract.	Comb.
Jas. A. Nelson	47	63	700	
J. D. Meador	25	55	1,000	
C. M. Crandall	52	73	1,200	1,000
S. D. Gregg	34	50	1,200	
F. J. Farr	95	146	1,500	4,000
J. H. Jones	40	105	700	2,000
L. W. Baldwin	150	207	2,825	3,175
P. Baldwin	130	145	900	4,000
S. W. Salisbury	64	100	2,000	500
E. M. Hayhurst		110		

Total 637 1,054 12,025 14,675

F. J. Farr, J. H. Jones and L. W. Baldwin winter their bees in cellars; all the rest winter them on the summer stands. E. M. Hayhurst is principally engaged in queen-rearing.

All bee-keepers within reasonable distance are invited to join or attend the meetings and help in bringing the bee-keeping interest more generally before the public, advance the production and extend the markets of its product. An invitation is also extended to all ladies interested in any way in bee-culture to be present and take part in the discussions of the association.

After a vote of thanks to the county papers and officers for favors extended, the association adjourned to meet at Independence on the last Saturday in April, 1883, at 10 o'clock a. m. P. BALDWIN, *Sec. pro. tem.*

Convention Notices.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883. C. T. LEONARD, *Sec.*

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, *Sec.*

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, *Sec.*
Kingston, Texas.

Articles for publication must be written on a separate piece of paper from items of business.

SELECTIONS FROM OUR LETTER BOX

Growing and Satisfactory.

I began bee-keeping in 1879, with 1 stray swarm; in 1880 I procured chaff hives; in 1881 I had 5 colonies in chaff hives; in 1882 I increased them to 28 colonies, mostly by dividing, and obtained 2,000 pounds of extracted honey, and 500 pounds of comb honey, and sold all of it at 12 and 16 cents per pound. A. MOTLAY.
Ottawa, Ill., Jan. 16, 1883.

"Nothing but Leaves" for Packing.

I had, in the spring, 5 colonies of hybrids and blacks, spring count; by natural swarming and dividing I increased them to 17 colonies; sold 1, and 2 colonies left me for parts unknown, leaving me 14 colonies packed in leaves. I obtained 375 lbs. of comb honey, and 75 lbs. of extracted. The above amount was received from 9 colonies. In Italianizing, they killed and lost 6 queens, which left me 4; with loss of time and delay, I can safely say that I lost 200 lbs. The 14 colonies in winter quarters have 50 lbs. of honey in each hive.

S. J. MCKENNEY.
Burlington, Iowa.

Statistics for Canada.

I would ask whether Dr. C. C. Miller wishes for statistics from bee-keepers in Canada as well as the States? Perhaps other readers of the BEE JOURNAL besides myself would like to know. H. F. BULLER.
Campbellford, Ont., Jan. 13, 1883.

[Of course Dr. Miller wants statistics for Canada as well as the States. Canada is rapidly advancing in bee-culture, and it will be quite interesting to know what she is doing.—ED.]

Binder for the Journal as Protection.

I think that the present "make up" of the WEEKLY BEE JOURNAL can hardly be improved; certainly not as suggested by Dr. Mason, for the reason that we want the advertising as well for reference as the rest of the reading matter, at least, as far as I am concerned. I would very much object to the soiling of any copy so that a part of it has to be thrown away. Let those who wish protection get one of the binders for the BEE JOURNAL. A. R. KOHNKE.
Youngstown, O., Jan. 18, 1883.

Wintering in Chaff and in the Cellar.

After receiving all my numbers for 1882, and looking them over in the Emerson binder, I can hardly refrain from writing to thank the editor and the many correspondents for such an excellent instructor in the art of bee-keeping. Last spring I had 4 colonies of Italian bees (2 being strong and 2 very weak); they increased to 10 strong colonies by natural swarming.

The increase all came from 2 colonies; and I took 120 lbs. of comb honey from them. I could have taken a quantity of extracted, but had no extractor, so thought I would keep it for spring feeding. After the honey season was over I sold 2 colonies, and bought 16 Italians and hybrids in Simplicity hives, at \$5 per colony. I packed 10 in sawdust, and 6 in chaff; the other 8 I put in the cellar. They are all alive yet, but I cannot tell how they will come out. I thank Mr. Heddon and Mr. Doolittle for their able articles in the BEE JOURNAL. These articles alone were worth more to me than the subscription price of the JOURNAL. We have had a pretty solid winter since November 23. The coldest being 13° below zero. HENRY CRUPE.
N. Manchester, Ind., Jan. 18, 1883.

An Old Foggy Bee-Keeper.

A neighbor of mine, who keeps bees, had a swarm of bees cluster on the body of a very fine and large apple tree, about 6 feet from the ground. He got the hand-saw, and down came the tree, to get the bees. If my neighbor that saws down apple trees to get his bees, when clustered on them, would read the BEE JOURNAL for one year, I think he would not saw any more trees down to hive his bees. E. DOTY.

Mackesburg, Iowa, Jan. 9, 1883.

Markings of Holy Land Bees.

Please tell me, through the columns of the JOURNAL, if the Syrian or Holy Land bees have any markings different from the Italians.

MISS L. E. DAVISON.
Caribou, Maine.

[That is a difficult question to answer. Mr. Jones says he can tell them by a "shield" on the body above the abdomen; Prof. Cook says the Syrian queens can be easily distinguished by peculiar "bars" across the abdomen. It is easier to distinguish them, however, by the extra amount of brood in the hive, and their sensitive dislike of jars.—ED.]

Italians Outstrip the Black Bees.

I started last spring with 9 colonies, all but one in box hives and log gums. I transferred them in April and May, but the cold and wet weather was very hard on the bees. I increased to 23 by natural and artificial swarming, but doubled back to 16; I have but 2 strong colonies, both Italians; my blacks stand no chance with them. While blacks are starving all around, my Italians are full and strong; I got about 50 lbs. per colony, spring count. After white clover bloomed I had to feed the bees and am still feeding them. I am the only person in this county that has taken over 30 lbs. of honey this season. I am trying to introduce the frame hive, but everybody is predicting failure for me; I hope they will be mistaken. This has been the poorest year for honey I ever knew. Bees, as a general thing, have not

gathered enough to winter on. The colonies I transferred were very large and my early swarms worked well. Here, in southwestern Kentucky, we did not see "the silver lining to the clouds," but I am thankful that others did. I did but little myself but I am truly glad that others have reaped a rich harvest. E. C. FRAZIER.
Hanson, Ky.

Weak Colonies, but Wintering well.

The season of 1882 was the hardest year on bees in this section (Eastern Ontario) that I can remember. Bees wintered well, but the spring and summer were very cold and wet; some bees having to be fed in June and July, to keep them from starving. They gained during the latter part of July and August, giving a few swarms and some surplus honey, but did not average more than 10 lbs. per colony, and went into winter quarters weak in bees, but seem to be wintering well so far. J. N. RAYMOND.

Newington, Ont., Jan. 10, 1883.

The Blizzard has Come.

The BEE JOURNAL is indeed a welcome visitor at our house, and, moreover, when other visitors take up the paper to read it, I do not feel ashamed at having such a fine-looking and useful weekly to present them. The Weekly JOURNAL is a perfect fit for me. It was a very favorable autumn for bee-keeping. The autumnal leaves fell from the trees after being tenderly nipped and were strewn with far less violence than is usual in our country. There were no tempests here, but when December came we caught a storm—caught a storm did I say, we called it a blizzard, etc., and we have got it again, and that is not all, we expect to have it for months to come. JOHN MORRIS.

Mauston, Wis., Jan. 15, 1883.

Bees Quiet in the Cellar.

I cannot brag of my success, this season, with bees and honey. I was away most of the summer, leaving the bees to take care of themselves, but I gave them a good supply of room to store in; being at home a few days in July and again in September, at which times I extracted, getting 110 lbs. of comb and 1,103 lbs. of extracted honey which I sell at home, the comb at 20 and 25c. per lb., and the extracted at 16c. per lb. I had 35 colonies in poor condition in the spring; sold 14, and increased again to 25, all of which are now in the cellar and very quiet; there are no dead bees on the floor yet; I had more than a bushel of them by this time last winter.

D. H. HOPKINS.
Bear Lake, Mich., Jan. 9, 1883.

Footer, not Foster.

I notice in the report of the Md., Va. and W. Va. convention that my name is printed Foster instead of Footer. I should not have called attention to it, but I have received a letter to-day from the post office, addressed to Thos. Foster and intended for me; this makes about 10 letters so

received in the last year, and all, I believe, from my name having been printed wrong in several papers. I am greatly in favor of these Bee Conventions and would strongly advise all bee-keepers to attend at least the nearest one, if they possibly can. At the Hagerstown convention it did me good to meet friends with whom I had had correspondence and dealing, but whose faces I had never seen. This association, though yet young and small in numbers, has in its ranks some very intelligent and progressive apiarists, men who have spent many years in the business, as honey producers and queen breeders. I have just read James B. Mason's article on a "Standard Frame." It is my opinion that when we get a universal frame we shall have a universal language and dialect.

THOS. FOOTER.

Cumberland, Md., Jan. 11, 1883.

A Candid Request.

Bee-keepers everywhere should qualify their reports, and not exaggerate, showing such large and enormous yields of honey from spring counts, and let the inquisitive and candid apiarists know from how many colonies they get their large yield. Now, let us figure a little. Scientific calculations are, in a good season of honey flow, that a bee will gather a teaspoonful during the season, and a colony of bees will average from 20,000 to 25,000; half of them in the field would obtain 12,500 teaspoonfuls, and if that will make 1,200 lbs. of honey, they must have large spoons in Texas. It looks to me a little exaggerated. There are some others who claim 800 lbs., 500 lbs. or 400 lbs. per colony. I have the highest respect for intelligent and scientific statements, but have no relish for exaggerated statements.

S. J. McKENNIE.

Burlington, Iowa.

[In some of the enormous yields of honey reported, we are assured that the colonies are doubled up to the capacity of 4 or 5 ordinary hives by extra stories, one over another; if so, the statements are unfair, and mislead the unsophisticated. Such reports may be true in fact, but totally unfair, and therefore quite unreasonable.—Ed.]

Wintering in Sawdust.

I moved into the woods in Marathon county, Wis., Oct. 24, 1880, and had 6 colonies of bees. Before spring I lost all, with dysentery. Last June I bought a colony of Italians that covered only part of three frames. I fed the some old honey, and they gave 2 natural swarms. I bought 2 queens and made 4 colonies by dividing. They all have over 25 lbs. of stores each, except 3, which had 45 lbs. divided between them. I have 5 combs full of odd-sized frame that I can feed them. I only had 3 six-pound boxes of surplus. We had much rainy weather last summer. I winter them in a sawdust house. There are no bees within 4 miles. I

have hard and soft maple, basswood, and white clover pasturage. We have got 15 inches of snow and no frost in the ground yet.

EDWIN BUMP.

Marshfield, Wis., Dec. 25, 1882.

Mr. Heddon's Feeder.

In the JOURNAL of Oct. 18, 1882, Mr. Heddon says "It takes only 24 hours time to give them (the bees) 25 lbs. of liquid food through our feeders, and they will put it in a proper position in the hive." Will he be kind enough to give a description of this feeder, through your columns, as I have no doubt it will be of great service to many beside myself. As I find that bees do well in the winter on sugar syrup, which, in this country, is not a quarter the price of honey, I should like to extract all my honey in the autumn and give the bees syrup to refill their combs; but having very little time to devote to my bees, the time that would be required to go round a number of hives to give them enough for winter, by a pound or two at a time, would be more than I could spare. Mr. Heddon's feeder would help me, and doubtless many others, out of a difficulty; and I therefore hope he will give us a full description of his feeder, and thus increase the debt of gratitude we already owe him for his able articles.

J. R. WILLIAMS.

Porthywaen, Oswestry, England.

A Telephone Connected to each Hive.

I vote for the editor to shape the "make-up" of the BEE JOURNAL, to his own notion. The readers can find the editorials, let them be where they may. I see that one of the writers in the BEE JOURNAL of Jan. 17, has been thinking with me in regard to having combs built in frames, then cut and placed in small sections, any size, even to nickel packages, and then placed in a hive to have them fixed up. I have been thinking again. Why not have some kind of a telephone arrangement attached to each hive, so that we can, at any time, hear from our bees. We could soon learn to know by the sound, whether or not all is well; then, at any time in winter, if a colony is not doing well, we can know it and remedy the trouble, if we can. I do not know much about the construction of the telephone, but I do believe one of a cheap kind can be made to do service in the way suggested. My 35 colonies of bees are wintering finely, up to this time. They are on their summer stands, with chaff cushions in the caps.

ISAAC SHARP.

Waveland, Ind., Jan. 19, 1883.

It is not yet a quarter of a century since the first Italian bees landed on our shores, and in this limited time they have been improved both in looks and in honey-gathering capacity. I am bold to assert that there are breeders of this race in America, whose queens will average better in looks, in vigor and in prolificness—workers better for business—than queens that come from Italy to-day.—Dr. J. P. H. Brown.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES for 1883.

20 cents per line of space, each insertion.

For either the Weekly or Monthly Editions.

A line of this type will contain about 8 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance.

Editorial Notices, 50 cents per line.

SPECIAL RATES.—Advertisements will be inserted in both Weekly and Monthly editions, at the following prices, if wholly paid in advance:

SPACE.	One month	Two mo'ths	Three mo'ths	Six mo'ths	One Year.
1 in. 12 lines	10.00	18.00	25.00	38.00	50.00
2 in. 24 lines	20.00	32.00	40.00	60.00	80.00
3 in. 36 lines	25.00	40.00	50.00	75.00	100.00
4 in. 48 lines	32.00	50.00	65.00	90.00	125.00
5 in. 60 lines	40.00	60.00	75.00	110.00	150.00
6 in. 72 lines	45.00	70.00	90.00	130.00	175.00

For the Weekly alone, 20 per cent. less than the above rates. On yearly advertisements, payments may be made quarterly, but must be in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

The BEE JOURNAL is mailed at the Chicago post office every Tuesday, and any irregularity in its arrival is due to the postal employees, or some cause beyond our control.

Our Premiums for Clubs.

Any one sending us a club of **two** subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For **three** subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For **four** subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For **five** subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The time for the usual winter rush of correspondence is here, and we wish to impress upon all our patrons the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but should be written on separate pieces of paper.

Local Convention Directory.

1883.	Time and Place of Meeting.
Feb. 3.—	Northern Ohio, at Norwalk, O.
8.—	Maine State, at Dexter.
	Wm. Hoyt, Sec.
14, 15.—	N. E. Ohio and N. W. Pa., at Andover
	C. T. Leonard, Sec.
March 13.—	Lorain Co., at Elyria, Ohio.
	O. J. Terrell, Sec., N. Ridgeville, O.
April 5.—	Utah, at Salt Lake City.
	E. Stevenson, Sec.
17, 18.—	Texas State, at McKinney.
	Wm. H. Howard, Sec.
28.—	Western, at Independence, Mo.
	S. W. Salisbury, Sec.
May 11.—	Iowa Central, at Winterset.
	J. E. Pryor, Sec.
—,	Texas State Convention, at McKinney.
	Dr. W. R. Howard, Sec.
Sept. 12-14.—	Tri-State, at Toledo, Ohio.
	Dr. A. B. Mason, Sec., Wagon Works, O.
Oct. 17, 18.—	Northwestern, at Chicago, Ill.
	Thomas G. Newman, Sec.
9, 10.—	Northern Mich., at Sheridan, Mich.
	O. R. Goodno, Sec., Carson City, Mich.
Dec. 5-6,	Michigan State, at Flint.
	H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Subscription Credits.—After sending subscriptions to this office, we would respectfully ask every one to look at the label on the wrapper of the next two papers, and there they will find the credit indicated thus: Those who have paid for the first six months of this year will find "June 83" after their names. Those who have paid for the whole year will find "Dec. 83" on their papers. The credit runs to the end of the month indicated.

The credit given on THAT LABEL is a sufficient notification of subscriptions due and receipt for payments made. If not so indicated within two weeks after sending money to us, you may be sure something is wrong, and should write to us about it. It will save annoyance and trouble if our subscribers will give this matter due attention.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

CLUBBING LIST.

We supply the **American Bee Journal** and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

Publishers' Price. Club	
The Weekly Bee Journal.....	\$2 00..
and Gleanings in Bee-Culture (A. I. Root) 3 00..	2 75
Bee-Keepers' Magazine (A. J. King) 3 25..	3 00
Bee-Keepers' Exchange (Houk & Peet) 3 00..	2 75
Bee-Keepers' Guide (A. G. Hill).....	2 50.. 2 35
Kansas Bee-Keeper.....	2 60.. 2 40
The 6 above-named papers.....	6 35.. 5 50

The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth) 3 25..	2 75
Bees and Honey, (T. G. Newman).....	2 75.. 2 50
Binder for Weekly Bee Journal.....	2 75.. 2 50
Apiary Register for 100 colonies....	3 50.. 3 00
Apiary Register for 200 colonies....	4 00.. 3 50

The **Monthly Bee Journal** and any of the above, \$1 less than the figures in the last column.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on *at least one new* subscription with your own? Our premium, "Bees and Honey," in cloth, for one *new* subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

One of the largest seed establishments in the United States is located at Marblehead, Mass., and is owned and managed by James J. H. Gregory. Mr. Gregory has earned a reputation second to none throughout every State in the Union, of selling the most reliable seeds that can possibly be obtained.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., January 22, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The supply of extracted honey is fully up to the demand. My quotations are: 7c. for dark and 9c. for light, delivered here.
BEESWAX—It is quite scarce. I am paying 27c. for good yellow wax, on arrival; dark and off colors, 17@22c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand is good for extracted in barrels as well as in glass jars and tin buckets; arrivals are fair. The demand is fair for comb honey, which, however, is not cheap enough to make trade lively. Extracted brings 7@10c. on arrival; comb honey, 14@20c.
BEESWAX—Is scarce and brings 20@27c. on arrival.
CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—January month, and still there is a large surplus of comb honey on the market. Prices are weak owing to large offerings, and anxiety on the part of shippers and holders here to realize on the product. Extracted honey is steady, but the demand is light.
We quote: white comb honey, in 1@2 lb. sections, 17@18c. Dark comb honey, hardly any demand. It is held at 12@15c. Extracted—White brings from 9@10c.; dark, 8@9c.; kegs, half-barrels and casks bring about same price.
BEESWAX—Yellow, 30@32c.; dark, 27@28c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Nothing of consequence is at present doing. There is no special inquiry, and no selling pressure, unless it is on off qualities.
White comb, 17@20c.; dark to good, 11@13@14c.; extracted, choice to extra white, 8@9@10c.; dark and candied, 7@8c.
BEESWAX—We quote 25@28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Strained, at 6@7½c. was salable—one lot of 17 bbls. bringing inside figure; but comb, very dull at 16c. to 18c.; and extracted do, 8@9c.
BEESWAX—Prime bright steady at 27@28c.
W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Has changed in price a very little, we find it necessary to sell all grades about 1 cent per lb. less. Best white, in 1 lb. sections, 20@21c. per pound; in 2 lb. sections, 18@20c. Extracted is very dull indeed, hardly any sale.
BEESWAX—Scarce, 28@30c.
A. C. KENDAL, 115 Ontario Street.

NEW YORK.

HONEY—Strictly choice to fancy white clover honey, continues in light supply and prices held firmly. Buckwheat and extracted honey quiet and unchanged.
We quote: White clover, first quality, 1 lb. boxes, 24@25c.; fair to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c.
BEESWAX—There is only a moderate demand for wax, but the supply is not large and prices firmly held for price 30 cts.
Western pure, 30@32c.; southern, pure, 31@33c.
D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX—30c.
CROCKER & BLAKE, 57 Chatham Street.

Send a postal for circular. It tells you about the handiest clamp and most perfect sections and cold-blast smoker. F. B. Broomhewer, Gallupville, NY

Bees for Sale.

50 Colonies of Bees, in Gallup frames, cheap.
200 Colonies of Bees, in Langstroth frames in prime condition.

J. H. ROBERTSON,

36wtf Pewamo, Ionia Co., Mich.

STUDENTS
IN BEE-CULTURE.

Having had such good success for two years past in teaching the theory and practice of honey-producing, I have now made arrangements to accommodate a large class during the coming season. I shall aim to give a five months' instruction, at the end of which time I hope and expect to turn out bee-keepers competent to profitably engage in the pursuit, or such as will be sought for as assistants, at wages above common laborers. All interested, write for terms.

BEE-KEEPERS' SUPPLIES

on hand, as usual. Beeswax wanted.
JAMES REDDON, 1*tf
Dowagiac, Mich.

LIVE BEE-KEEPERS WANTED,

to introduce the new lime cushion, the only protection yet discovered that will carry the bees safely through winter and spring without fail. Send \$3.00 for right to retail this cushion in your county, or send \$3.00 for one apirary right to patentee. Remit by registered letter or P. O. order.

F. DELLA TORRE,

74 Charles-st. Avenue, Baltimore, Md.
Patented April 25, 1882. No. 254,932. 45w13t

THE CONQUEROR.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent postpaid for \$2. Address,

BINGHAM & HETHERINGTON,

Abronia, Mich.

BIND YOUR JOURNALS
AND KEEP THEM
NEAT AND CLEAN.

The Bee-Keeper's Guide;
OR,
MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the
State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees, full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who contains it, will ever regret having purchased.—*Mich. B. J.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is truly up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—WM. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABEE DU BOLS*, editor of the *Bulletin D'apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *volume* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. Of taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has but the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00 by mail prepaid. Published by

THOMAS G. NEWMAN,

West Madison Street, CHICAGO, ILL.

My Vegetable and Flower Seed Catalogue for 1882 will be sent FREE to all who apply. Customers of last season need not write for it. All seed sent from my establishment warranted to be both fresh and true to name, so far, that should it prove otherwise, I agree to re-ship the order gratis. My collection of vegetable seed is one of the most extensive to be found in any American catalogue, and a large part of it is of my own growing. As the original introducer of Early Ohio and Burbank Potatoes, Marblehead Early Corn, the Hubbard Squash, Marblehead Cabbage, Phinney's Melon, and a score of other new Vegetables, I invite the patronage of the public. In the gardens and on the farms of those who plant my seed will be found my best advertisement. James J. H. Gregory, Marblehead, Mass.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the *Weekly Bee Journal*.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, **75 cents**; in paper covers, **50 cents**, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 165 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

A Liberal Discount to Dealers by the Dozen or Hundred.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,
825 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. (Cloth, \$1.25; paper cover, \$1.)

Quinby's New Bee-Keeping. by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture. by A. I. Root.—This contains "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book. by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit. by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c; in paper covers, 50c., postpaid.

Bienen Kultur. by Thomas G. Newman, in GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory.—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine. by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as Food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market. including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Foul Brood. its origin, development and cure. By Albert R. Kobake. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Duda, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 10c.

Bee Pasturage a Necessity. by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. Price 5 cents.

Bees in Winter. with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. Price 5c.

Queen-Rearing. by Henry Alley.—A full and detailed account of TWENTY-THREE years' experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price \$1.00.

Food Adulteration. What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 54c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and plans by Doyle's Rule, cubic contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35 c. postpaid.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Moore's Universal Assistant, and Complete Mechanic. contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. Ask your bookseller for it. Sent post-paid for 40 cents.

Chicken Cholera. by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Deutsche Buecher, Ueber Bienenzücht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände—Derlichkeit des Bienenstandes—Honig pflanzen—Erziehung der Königin—Füttern—Schwärmen—Ableger—Verfäulen—Stalieren—Rüfeln von Königinnen—Ausziehen—Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschrieben ist. Preis 40 Cents.

Honig als Nahrung und Medizin.—von Thomas G. Newman. Dieses enthält eine klare Darstellung über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigtuchen, Formküchlehen, Puddings, Schaumkonfekt, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Konsumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten.—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdekrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Rezepte. Preis 25 Cents.

Bees as Fertilizers of Flowers.

In fructifying the various flowers bees act as Nature's marriage-priests, and present us with a field of study as boundless as the gorgeous realm of Nature's bloom. But for the oft-repeated visits of the bees, many a beautiful flower would, in a short time, cease to bloom—aye, and also to live! Many plants absolutely require the visits of bees or other insects to remove their pollen-masses, and thus to fertilize them.

Hence, Darwin wisely remarks, when speaking of clover and heart-seed: "No bees, no seed; no seed, no increase of the flower. The more visits from the bees, the more seeds from the flower; the more seeds from the flower, the more flowers from the seeds."

Darwin mentions the following experiment: "Twenty heads of white clover, visited by bees, produced 2,990 seeds; while twenty heads, so protected that bees could not visit them, produced *not one seed*."

Prof. Beal, of the Michigan Agricultural College, has been conducting experiments, for the past six years, with bumble-bees and red clover. The sixth experiment, during 1882, he describes as follows:

Two fine bunches of the first clover crop, apparently alike, were both covered with mosquito netting. No insects were seen about either, except what are mentioned below. On June 29th, a bumble-bee was placed inside of one netting and seen to work on the flowers; July 10th, two more were introduced and seen to work, and on the 12th, more were put in and observed. On July 31st, fifty ripe heads were selected from each plant and the seeds carefully counted. The fifty heads on the plants where bees were

excluded yielded twenty-five seeds. The fifty heads on the plant where the bumble-bees were inserted under the muslin, and seen to work, yielded ninety-two seeds. This is nearly four times as many as were produced by heads where the bees were excluded.

In all instances, the heads were seen to be unopened, when they were covered with muslin or paper sacks. In the last experiment, as well as in the others, perhaps the bees did not visit all the flowers. Insects, even in the most favorable seasons, are not always to be relied on to transfer pollen enough to fertilize all the pistils. Prof. W. W. Tracy has found in several seasons, where he has raised Hubbard squashes on a large scale, that he increased his crop of fruit quite largely by artificially transferring pollen with his own hand, every day or two, during flowering.

To see how the uncovered heads of red clover from different plants varied in the number of seeds produced, I selected fifty heads from five plants near each other, where each had plenty of room. This was the second crop of clover. Fifty heads from each plant yielded as follows: 1,260, 1,275, 1,460, 1,485, 1,820 seeds respectively. In another place, fifty heads yielded 2,290 seeds, or nearly twice as many as plant number one in the lots just above noticed. It is a fair conclusion that bumble-bees are of considerable value in fertilizing the flowers of red clover.

Statistical Reports.

Dr. Miller writes us that he is daily receiving "a steady stream of postal cards" covering the whole ground, "from Canada to Texas." As each one helps to swell the aggregate, we hope they will continue, until all are sent in. The Doctor adds:

A correspondent asks what should be the report of wax, from one who uses his wax in making foundation. I suppose each one should report all his wax, whether he uses or sells it. Several say they will send in reports of others, if desired. By all means, let us have all we can.

Certainly; all honey and beeswax should be reported, no matter whether used by the bee-keepers themselves, or sold and used by others.

Dr. Miller assures us that "from present appearances we shall get fuller

statistics than ever before." This is very encouraging; but, probably, some are neglecting the matter, thinking it will make but little difference about one report; others may think, because they have given a report in some bee paper, or at a convention, that such is sufficient. A moment's thought, however, will dispel these delusions. The many, even if comparatively small, will swell the grand total. Some have asked "if we send in the reports of our neighbors, may they not be duplicated?" No; the reports are all classified by States and each person's name is recorded, so that duplicates are impossible. If you have neighbors, that you have good reason to think have neglected it, send in the reports for them, and, in this way, aid the work all in your power. As this is our LAST CALL, please attend to it *at once*.

Do not send to us, but address them to "Dr. C. C. Miller, Marengo, Ill."

Our readers will notice that the BEE JOURNAL is this week "made up" with a cover, which may be removed or retained in binding the year's numbers, to suit the wishes of the owner of the volume. We have found that a great majority prefer this plan, and so have adopted it permanently.

The Rev. Thomas Pope Hodnett, pastor of St. Malachy's Church, Chicago, has placed a neat pamphlet of 64 octavo pages on our desk. It contains a variety of "matter for family reading and instruction,"—several sermons, poetry, facts, figures, letters, etc., by "Father Hodnett," who is an enthusiastic and zealous Catholic priest, by whose exertions a very handsome church has just been erected on the corner of Walnut Street and Western Avenue, only a few blocks from our office. We have read several portions of the pamphlets with more than ordinary interest, and have laid it away for a more thorough perusal in the future.

The Paraffine and Glucose Story.

We have received the following letter from Mr. J. W. Porter, Charlottesville, Va., dated Jan. 18, 1883:

DEAR EDITOR:—In yesterday's Cincinnati *Commercial Gazette*, weekly, appears a remarkable editorial article on "Food Adulteration." I have, by this mail, written them a letter, which, if published, will tend to correct the impressions such an article would produce, when the public mind is so sensitive on the subject of adulteration.

I take the ground that comb honey is almost the only unadulterated sweet on the market, and such, because the cupidity of man has devised no way to profitably substitute a counterfeited article. Let us, one and all, labor for legislative protection against food adulteration, until we get as full protection as the law gives the Englishman.

The following are the paragraphs referred to by Mr. Porter, contained in the editorial article of the Cincinnati paper:

"It used to be considered safe to use honey in the comb, but now nearly all this is manufactured."

"At first pure honey was extracted from the comb, and the bees were fed on glucose, from which the comb was rapidly refilled, but now, artificial combs are produced, and bees being fed on glucose, so-called honey is turned out in comparatively large quantities, and bees, at the same time, are being demoralized."

The editor of the *Commercial Gazette* has been imposed upon by that man "Wiley," who invented the "paraffine comb and glucose" story as "a joke," as he stated in the *Indiana Farmer* last June, which was copied into the *BEE JOURNAL* of June 14, 1882, and commented upon.

Mr. Wiley's own version of the origin of the story [lie], and our remarks, are as follows:

Perhaps it may be well enough to give here the origin of the "paraffine comb" story which has appeared, I believe, in almost every publication in the country. The original appeared in the *Popular Science Monthly* for June, 1881, in an article entitled "Glucose and Grape Sugar," which I contributed to that number, and on page 254, occur the following words: "Bees eat glucose with the greatest avidity; or rather, they act as funnels by which the glucose is poured into the comb. For it is quite true that the honey made by bees which have free access to glucose differs scarcely at all from the glucose itself. But the quantity of honey which a bee will store away when fed on glucose is truly wonderful. This gluttony, however, rapidly undermines the apian constitution, and the bee rarely lives to enjoy the fruits of its apparent good fortune. In commer-

cial honey, which is entirely free from bee mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery.

This last clause which, when written, was meant for a *scientific pleasantry*, came near throwing the whole bee world into epilepsy. It appears that persons who devote themselves to *BEE JOURNALS* undergo a certain cerebral inspiration which renders them incapable of seeing a *joke*. The only point which they can appreciate seems to be the sting of a bee.

The rejoinder reminds us of an anecdote we heard many years ago, located in a rural district in Indiana. A well-to-do farmer lost a very fine filly from his pasture-lot, and after several days' search found it snugly tied in the log barn of a distant neighbor of doubtful repute. The neighbor was indicted, tried, and found guilty of larceny; when the Judge asked what he had to say, why sentence should not be passed, he put in a plea that the animal was only taken for a joke. The Judge inquired how far his barn was from the pasture lot, to which he replied, "about 5 miles." "Well," said the Judge, "that is carrying a joke too far; hard labor in the penitentiary for seven years." The writer above says he contributed to the *Popular Science Monthly* his "paraffine comb" story [lie] about a year ago, "which has appeared in almost every publication in the country." The latter part of the article, however, was only meant for a *scientific pleasantry*.

Do scientific men indulge in *pleasantries* which will cast a gloom over thousands of honest producers throughout the country, and depreciate the value of their product by creating a prejudice against it? For nearly a year this *scientific joker* saw his fabrication published in nearly all the papers in the country, and reiterated from across the ocean, and yet he lacked the manhood to affirm it a joke until the "*BEE JOURNAL* man" counteracted its influence by showing the falsity and absurdity of the article. Whether it be true, as has been often intimated, that the story was instigated by parties interested in the glucose traffic, in retaliation for the hostility of the bee men to their frauds, we cannot affirm; but we do believe it originated with no honest intention.

☞ We have a few copies of our pamphlet entitled "*Bee Culture*" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Iowa State Convention.

Mr. M. Sorrick, Des Moines, Iowa, has written us as follows concerning the practicability of holding a State Convention, and getting up a good Bee and Honey Show at the next Iowa State Fair in that city. He says:

MR. EDITOR:—Ought there not to be a State Convention in Iowa? It seems as if we were getting behind in the matter of not having a State Convention. As the State Fair is located at Des Moines, for 1883, I should like to see a State Bee-Keepers' Convention some time during the Fair week, if not sooner; as this is a central point. At that time there will be a good many bee-keepers here from all parts of the State, as well as other States. Would not that be a good time to get the bee-keepers together? I really think there ought to be an organization sooner. I should like to hear what the other bee-keepers of Iowa think of the matter.

We have had steady cold weather since December 25, with good sleighing; the snow is two feet deep, on the level. Half of my bees are under a snow drift, where I shall leave them, without disturbing them until the weather moderates. Then I will dig them out and clear out the entrances.

M. SORRICK.

Des Moines, Iowa, Jan. 18, 1883.

As Iowa is a grand field for bee-keeping, and as it contains a large number of wide-awake, progressive apiarists, we see no reason why it should not have a State organization, and a very large and creditable display of honey and bees at the forthcoming State Fair.

The very interesting lecture lately delivered by the Rev. O. Clute before the State Agricultural Society, should have made that body favorable to the bee and honey interests, and we hope to see very liberal premiums offered by the Board. Mr. Clute is one of the best of public speakers—interesting and eloquent—and he is, withal, a *thoroughly practical and progressive* bee-keeper. If he can be enlisted to labor with the Board, we have no doubt but that he can secure premiums, as liberal as have Mr. Cutting and Prof. Cook, of the Board of the Michigan State Agricultural Society. We think all it needs is a little united action among apiarists, and they can secure all the premiums that they can consistently ask for. "*Ask and ye shall receive*" is a promise, trite but true. Try it.

☞ Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

Bee Culture in the Rockies.

There are many inquiries now about bee-culture in Colorado. In order to reply to the many, all at once, we give the following from the *American Agriculturist* for January:

Apiculture is an established industry in Colorado. A recent tour through all the valley lands, in search of agricultural statistics, gave the writer full evidence that both in Northern and Southern Colorado more or less attention is being paid to that pleasant and profitable industry; and that, if it increased in the same ratio for the next ten years, at that time the market could be supplied with the home product to the entire exclusion of that now brought from Kansas and California. We are inclined to believe that at least five thousand colonies of bees, mainly Italian, are in the State; that Colorado is as well adapted to profitable bee-keeping as California; that the honey produced is full as white, as pure, and as sweet as any introduced into the market; that there is hardly a farm or garden where bees will not thrive, and that the foot-hills are peculiarly adapted for extensive apiaries.

In the East, warm weather, with occasional storms, is necessary to a good honey season. A continual drouth is fatal to the bees' harvest. Looking at Colorado from this point of view, it would seem as if its arid climate would be unfavorable. But the belief now prevails, that the hot days, followed so invariably by cool nights, facilitate the secretion of honey in flowers and blossoms better than any other state of weather. In the East, days of drouth are usually followed by warm nights, which is fatal to honey prospects. Occasional showers cool the atmosphere, which is favorable; therefore, the temperature is of more importance than dampness. Again, continual rains destroy the honey crop, and deprive the bees of an opportunity to go upon the wing. Taking these things into consideration, we see why bees do so well in the dry climate of Colorado. Its hot days, following by cool nights, give to nature an abundance of sweets. With no prolonged rains, bees have an ample opportunity to improve the shining hour, which in Colorado means from sunrise to sunset, one day after another, week in and week out—as a rule.

Where a canyon or gulch is open or wide, and the hills are low, a dry side gulch with a southeastern exposure would be a good situation. In the early spring the bees go to the lowest foot-hills to get the earliest-blooming flowers, and as the same varieties blossom at higher altitudes, they follow them up, and as the season advances, still keep following them up higher and higher. Then, as new varieties bloom below, they repeat the process during the entire season of bloom. But it is also to be said that bees will do well upon the plains, in the valleys, and wherever land is under cultivation; for the face of nature here is covered from early spring-time to

late fall, with flowers that afford honey in great abundance. Trees, wild blooms, vegetable blossoms, wild grasses, cleome, alfalfa, corn blossoms, all offer their store of sweet treasure to the ever busy bees. In considering this source of constant supply, it is a fact of great importance to know, that from the early part of March, generally, bees begin to gather pollen and honey from willows on southern hill-sides and sunny slopes, and from this time to October, there are very few days that honey is not gathered from some source.

Now contrast this with a season in the Eastern, Middle, or even Western States, where the honey season seldom lasts three months, and it will be seen that Colorado is one of the best States in the Union for bee-culture. Pasturage is profuse in its abundance. With the willow blossoms comes a species of *Delphinium*, pushing its head up through the snow, and covering foot-hills and plains with its bloom.

Roses and red raspberries abound in the foot-hills. On the plains, with the willow and cottonwood, comes a little weed called the "hog potato," growing flat on the ground. It has a purple bloom. Then there are fruit blossoms and wild roses in May and June; milkweed and immeasurable wild flowers also appear. Alfalfa is in its first bloom and is favorite foraging ground for the busy bees. In July the wild grasses and wild flowers tempt the roving fancy of the bees, while melon, squash, and other vines invite the winged seekers after sweets. During August and September, corn tassels, alfalfa, amber cane, furnish abundant food. At this time, too, the prairie, in spots, are covered with cleome, or the Rocky Mountain bee-plant, with its wealth of purple flowers, in which lies hidden an amount of bee-food one little dream of, which the bees transform into the choicest honey that can be found. In October, there grows on dry prairie land, a weed, the shape and size of sage brush, having a yellow bloom. This is not the best bee-food known, but it is used when other things are not to be had.

There is one drawback to bee-culture which must be mentioned. It comes from too much warm, sunny weather in winter. This causes bees left on summer stands to fly out, and doing this day after day, many are lost and never return to the hive, and as they do not begin breeding until February, and then very slowly, the numbers rapidly decrease, and often the entire swarm is lost from this cause. The remedy for this is a good cellar, well ventilated, and so arranged that the temperature will be kept at 40° to 50° Fahrenheit. It is to be said, in addition, that perfect darkness and the greatest degree of quiet that can be secured must be maintained.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75.

Attractive Packages of Honey.

The following, from the *American Agriculturist*, is such advice as we have often given to bee-keepers, about having honey attractive, when marketing it for the retail trade. It cannot be too often stated, nor too persistently urged. If we want to popularize its consumption, it must attract the eye, and, by its neatness, captivate the purchaser. This advice is good and timely, and bee-keepers should "ever remember" it:

Winter is a good time to build up a market. For extracted honey, use attractive pails and jars, with neat labels, which state the kind of honey, and the name of the person that produces it. Neat pyramids of these packages, in the stores, will attract buyers. The size of the vessels should vary from one-half a pound to those that will hold five pounds. The label should state that the granulation is no injury, and, indeed, is the best assurance of purity. It should also tell how to restore the liquid condition, without harm to the honey, by applying heat, not to exceed 180° F.

Comb honey should be put in a neat case, so as to show off to the best advantage. The case ought to bear the name of the producer, and the kind and grade of the honey. Bee-keepers cannot be too careful about grading their honey. In creating a market, nothing will take the place of neatness and care in putting up the honey. If it properly arranged, every dealer will be only too glad to give it a showy place in his store.

☞ We wish to thank the many who have not only renewed their subscription to the BEE JOURNAL for 1883, but who have also sent on one or more new names with their own. The multitude of expressions of fraternal good-will and kind wishes for the success of the JOURNAL also call for our acknowledgment. We cannot find time to write to each one personally, and hope that all such will take this acknowledgment as though personally addressed to those who have so kindly aided us in our work.

☞ Mrs. Martha Adams Winder, wife of Mr. John W. Winder, recently from Thibodaux, La., died at Uvalde, Texas, of dropsy of the heart, on Sunday the 7th inst., in her 52nd year. Mrs. Winder is reported to us as a sincere and consistent Christian, and that, during her illness, she often expressed a wish to recover, so that she might be more useful in the church. Our sympathies are with the husband and the two sons, for truly the very heart of the home life departs when the mother is taken away.

Dampness and Bees in Winter.

Prof. Cook, in an exchange, refutes the idea that dampness is a cause of mortality of bees in winter. He says:

A writer on bee culture calls attention to the fact that honey, the winter food of the bees, is almost purely a hydro-carbon, and so needs little digestion, before it is absorbed into the nutritive fluid from the stomach. Then it is assimilated, and passes off as water and carbonic acid. Thus the excretion, in winter, is by respiration. That this may go on freely, the air must be dry. The writer then asserts, that in those winters most remarkable for the bee mortality, the air has been very moist.

An examination of the condition of the atmosphere as to the point of saturation, from accurate records taken three times daily, for the past twenty years, shows that there is not the least evidence in favor of the idea that excessive moisture was in any single case the cause of the great losses of bees. It also appears that in all the seasons of bad wintering, severe cold was experienced. It is further shown that when the cold occurred early in the winter, the mortality commenced at an early period. If late, the bees did not appear diseased until near the end of winter.

"Spence's Select Social Readings" is the title of a pamphlet of 126 pages, by Jacob Spence, Toronto, Ontario, Canada. This is an excellent manual of Readings, Recitations, and interesting Selections, admirably suitable for those who are desirous of giving readings, recitations, etc., at sociables, or gatherings for spending a pleasant evening. It covers the ground from "grave" to "gay," with rich and rare selections. Mr. Spence is one of Canada's progressive apiarists and a constant reader of the BEE JOURNAL.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

New Catalogues and Samples.

We have received Catalogues for 1883 from T. L. VonDorn, Omaha, Neb., and I. R. Good, Nappanee, Ind.

The following have sent us new Seed Catalogues: Jas. J. H. Gregory, Marblehead, Mass.; and J. W. Manning, Reading, Mass.

The Philadelphia, Pa., Record Almanac for 1883 is received, and is full of statistical and useful information.

J. V. Caldwell, Cambridge, Ill., and D. S. Given & Co., Hoopeston, Ill., have sent us very nice samples of comb foundation.

"There's no Time like the Old Time," is the title of a new song by Oliver Wendell Holmes, music by J. J. Roe, and published by W. W. Whitney, 111 Summit St., Toledo, O., a copy of which we have received, marked "With the compliments of the author."

Attention is called to our new and liberal advertising rates for 1883.

Convention Notices.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883, at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.
Kingston, Texas.

The bee-keepers of Northeastern Michigan are hereby requested to meet at the Dayton Hotel, in Flint, at 10 a. m. on Tuesday, Feb. 13, 1883, for the purpose of organizing a bee-keepers' association. All bee-keepers are earnestly requested to come, and to bring with them any apian articles of interest that they may possess. A free room, and reduced rates of board have been secured.

W. Z. HUTCHINSON.
Rogersville, Mich., Jan. 22, 1883.

The Tuscarawas Valley Bee-Keepers' Association will hold a meeting in the Town Hall in Coshocton, O., on Feb. 14, 1883, at 10 a. m. Every bee-keeper is wanted at this meeting. Every one interested in bees or honey is requested to be present.

J. A. BUCKLEW, Sec., Clarks, O.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nelle's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The second annual meeting of the Colorado State Bee-Keepers' Association will be held in Denver, on February 6, and continue two days.

D. S. GRIMES, Pres.

The next meeting of the Maine Bee-Keepers' Association will be held at Dexter, February 8th and 9th, 1883. A large attendance of bee-keepers from different parts of the State is expected, and it is hoped that it may be one of the most interesting meetings ever held by the Association. A large exhibit of hives and implements, used in the apiary, is expected; and all attending the meeting are earnestly requested to bring something to help make a good display. Any article sent to the Secretary will be placed on exhibition, and cared for, free of charge. The following is an imperfect outline of the programme for the two days: First day:—Secretary's report; Treasurer's report; reports of Vice Presidents of the different counties represented; President's address; choosing committee to award preferences on articles exhibited; reading of essays and discussions. Second day:—Election of officers; report of committee on articles exhibited; reading of essays and discussions. Essays are expected on the following subjects:—Feeding Bees; How to make Bee-keeping Profitable; Artificial Pasturage; The Coming Bee, etc., etc.

Ripley, Me. WM. HOYT, Sec.

The annual meeting of the Northern Ohio Bee-Keepers' Association will be held in Whittlesey Hall, Norwalk, O., Saturday, February 3, 1883. All bee-keepers are invited to attend and participate in the exercises. Subjects for discussion: Size of Frame; Size of Section; Best Method of Obtaining Surplus Honey, and various other matters of interest to all bee-keepers. S. F. NEWMAN, Sec.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883. C. T. LEONARD, Sec.

A \$20.00 Biblical Reward.—The publishers of *Rutledge's Monthly* offer twelve valuable rewards in their *Monthly* for February, among which is the following:

We will give \$20.00 in gold to the person telling us which is the middle verse in the Old Testament Scriptures by February 10th, 1883. Should two or more correct answers be received, the reward will be divided. The money will be forwarded to the winner February 15th, 1883. Persons trying for the reward must send 20 cents in silver (no postage stamps taken) with their answer, for which they will receive the March *Monthly*, in which the name and address of the winner of the reward and the correct answer will be published. This may be worth \$20.00 to you. Address RUTLEDGE PUBLISHING COMPANY, Easton, Pa.

CORRESPONDENCE

Beautiful Flowers.

S. W. DUFFIELD.

Ye are the eyes of the world,
With which the spirit divine
Looks, from a thousand nooks,
Full into mine!

Ye are the breath of the world,
With which the spirit divine
Breathes, through these fragrant wreaths,
A perfume fine.

Come from the ends of the world,
Ye flowers in waves of light!
Break on the souls that ache
Through all the night.

For the American Bee Journal.

The Carbonic Acid Gas Question.

S. CORNEIL.

The direction taken by the carbonic acid produced by the respiration of a cluster of bees is often a leading subject for discussion at bee-keepers' conventions. A large majority of those taking part in such discussions seem to be of the opinion that because the specific gravity of this gas is about one-and-a-half times that of atmospheric air, it falls to the bottom and accumulates or runs out at the lowest aperture, like so much mercury or water, some going so far as to assume that they can run it off from the cellar through the drain or ventilating pipe, while at the same time a current of pure air flows in the opposite direction. We are further told that it is necessary to raise our hives at least 10 inches to keep the bees out of the stratum of this gas, which will accumulate at the floor before spring. On the other hand a few bee-keepers, amongst whom I recollect the names of Dr. Southwick and P. H. Elwood, hold that this gas does not fall to the bottom, but that it is uniformly diffused through the air of the hive or repository. "The detection of this gas, and an exact determination of the amount of it contained in air, require skill, careful attention, and instruments and materials of analysis of much perfection." Fortunately, it is not necessary for bee-keepers to make original inquiries to decide whether it accumulates at the floor or becomes diffused through the apartment, because very careful experiments have already been made by some of the most prominent scientists of the present age, and the results of their investigations are such as to leave no difficulty in finding out the direction taken by the carbonic acid evolved by respiration.

The quantity of carbonic acid in air, "as pure as it blows on the hill tops," is on an average about 4 volumes in 10,000. The standard for good ventilation, fixed by the late Dr. Parkes, is that the ratio of carbonic acid shall not exceed 6 volumes in 10,000. The air exhaled contains one

hundred times the natural quantity. In the following table, it will be noticed that the proportion of carbonic acid is in most cases excessive. The variations at floor and ceiling are likely caused by currents of cooler air from outside.

TABLE OF ANALYSES FOR THE DETERMINATION OF CARBONIC ACID.

DeWetherill				

The following quotations are also to the point:

"Carbonic acid is so heavy that when quite pure, it can be poured like water from vessel to vessel, and yet, if a vessel of it is left open to the air, it will soon pass off and disappear. This is very important to us, otherwise the amount of this heavy gas produced would make the continuance of life impossible."—*Hartshorne, in "Our Homes."*

Dr. Mattson, author of "Facts for the People Concerning Health," says:

"This carbonic acid being heavier than common air, it is often supposed that it is precipitated to the floor as fast as it escapes from the lungs during the process of respiration. It would be unfortunate if this were true. Nature has provided against this difficulty through the well-known law which regulates the diffusion of gases."

"It is conceived by some that the carbonic acid of the breath, from its greater weight, must be chiefly at the bottom of the room, but this is a mistake. The heated breath ascends instantly, because it is, as a whole, lighter than the air around it, and the carbonic acid in it does not tend to separate from it and fall down by its own superior weight, but by the law of

the diffusion of gases seeks to spread itself equally all over the room, and would do so though it were lying at first on the floor."—*Chambers' Encyclopaedia.*

Dr. Wetherill, speaking of Loppens' experiments upon the air of unventilated rooms, says:

"These experiments, like those of Lassaigne and others, establish the fact that the carbonic acid of an unventilated room, is uniformly diffused therein, the slight difference being in favor of the ceiling, and not of the floor, as was formerly ignorantly assumed from the superior specific weight of this gas."

The following very important statement is taken from the final report of a board of United States officers, convened by request of a special committee, on the ventilation of the Capitol at Washington. Great weight attaches to it, because they had placed before them all that could be said in favor of the downward theory, and had fully considered the question in all its bearings.

"This carbonic acid gas, like all other gaseous impurities derived from respiration, is present in about the same proportion at all heights in the room, the percentage being nearly the same in samples of air taken from the top and from the bottom in ordinary apartments. In the hall the carbonic acid is slightly in excess at the top. It is a gross error to suppose that this gas falls to the floor of the house, for, although when pure, it is heavier than atmospheric air of the same temperature; yet air expired from the lungs, is higher than the surrounding air at ordinary temperatures, and the law of the diffusion of gases effectually prevents any separation."

The report is signed as follows: Joseph Henry, Secretary of the Smithsonian Institution, President of the Board; Thos. Lincoln Casey, Lieut. Col. Corps of Engineers, Member of the Board; Edward Clark, Member of the Board; F. Schumann, Civil Engineer, Member of the Board; and J. S. Billings, Surgeon U. S. Army, Secretary of the Board.

I trust the foregoing will be of some assistance to our friends in deciding for themselves what becomes of the carbonic acid. I propose having something further to say on the other principal product of respiration, aqueous vapor, at a future time.

Lindsay, Jan. 25, 1883.

For the American Bee Journal.

Catnip as a Honey Plant.

T. ELLICOTT.

I believe little is known as to the amount of honey bees get from it, and it is not strange that it is so, when one thinks of the quantity growing, and the number of bees to work on it. I think it is never neglected (while in blossom) by the bees; at least, I never have seen it when bees did not visit it from morning until night. The amount growing is far less than one would suppose. Let

any one take up all the plants growing in an old village, and I think he will find there is far less than he supposed.

I tried getting plants in that way to set in a piece of ground which I had prepared to receive them, and was much disappointed in the number I found, but was not at all disappointed during the past season, with those I set out, when I found them thronged with bees from morning until night, all the time they were in blossom; and then in the fall they blossomed a second time, and were worked on by bees until the frost killed them. Let any one devote a small piece of ground to catnip, and watch the bees work on it, and I believe any one who does so, will be satisfied that there is not a plant that grows that has more attraction for bees, and one must suppose that bees do not work on it for nothing, when, if they watch other plants, they see them deserted as soon as the honey flow ceases.

Much is said about buckwheat for bees; it is often neglected by them, and I think they never work on it all the day long, and therefore I conclude that bees get some honey from catnip all the time. There is not enough of it in any one place for them to get quantity enough to be observable as catnip honey, but I have no doubt it adds to the yield we get, and is excellent for the bees; therefore, I say, plant and spread it as much as possible. I take a great deal of pleasure, seeing bees work, and much interest in the cultivation of honey plants. I like to see the bees enjoy themselves, which I believe they do, far more when at work; for, when not at work, they are always cross.

Fentonville, Mich., Jan. 20, 1883.

Indiana State Convention.

According to programme, the fourth annual meeting of the State Bee-Keepers' Association commenced at the rooms of the State Board of Agriculture, Indianapolis, Ind., Jan. 10. On account of the inclemency of the weather, the members came in slowly; but the meeting was called to order a few minutes after the time set, 10:30 a. m., Mr. Cotton in the chair, with all the officers present. After some preliminary work the society settled down to business.

Mr. Buntain said he was a beginner, had come to the meeting for the purpose of learning. He was full of young America, and wanted to learn to handle bees without having to wade through the sloughs which had been traveled by the pioneer bee-keepers present, and hoped the older members would take hold of the work and push it right along.

The president called attention to the death of Mr. Bellman, a former president of the Association, and appointed a committee to take action on the matter, consisting of Messrs. O'Rear, Robinson and Mrs. Robinson, after which the meeting adjourned until 2 p. m.

On re-assembling after the dinner hour, the secretary read a communi-

cation from Prof. A. J. Cook, Lansing, Mich., on clipping queen's wings, in which he said, I have practiced this method of bee management now for years, and have yet to see the first evidence that the bees take umbrage at the proceeding. In the matter of statistics, he hoped the Society would agitate the matter and do all it could to assist the committee appointed by the North American Society. He hoped this and all other State Associations would strive to assist the North American Society. Happily, civilization is opposed to selfishness; we are all interested in our neighbor's success. Let the Los Angeles bee-keeper put up his honey in a slip-shod shape, and the Maine bee-keeper loses by the act. The subject of the paper was discussed at some length, and it seemed to be the voice of the convention, that the clipping of the queens' wing was no hindrance in the management of the bees.

The following, from the question box, brought out a lively discussion: "Are queens reared under the impulse of the swarming fever, superior to those reared from the egg artificially?" Many of the members had tried both plans extensively, and while some very poor queens were produced artificially, with proper care, equally good ones could be reared as those produced under the impulse of the swarming fever, and this seemed to be the voice of the Society.

The question: "Are Cyprians more vindictive than the Italians?" occupied the time of the meeting at some length, and led to some very amusing incidents in the handling of bees, and while some of the members claimed to have very gentle Cyprians, all of those who had them, of known purity, testified to their ability to hold their own with any bee-master, regardless of smoke, sweetened water, or even chloroform. However, it was concluded that they had some very good qualities which were to give material assistance in producing our great expectant—*Apis Americana*.

"Dividing, or Natural Increase" was the next question of importance under discussion.

Mr. Muth thought that the first object to be sought was the honey crop, and the increase made afterward, and that very much depended on condition and circumstances. For people who paid but little attention to their bees, he thought it best to allow the bees to increase naturally, but to those who gave the necessary care to them, the plan of a gradual increase artificially was the best plan. After some further discussion the matter was passed for the present to allow the president to deliver his address.

PRESIDENT COTTON'S ADDRESS.

Ladies and Gentlemen of the Indiana Bee-Keepers' Association: This is the fourth annual meeting since our organization; each year increasing in interest; each member being ready to give a reason for the faith that is in him, in regard to the little busy bee. Our Society is organized

on philanthropic principles for the general dissemination of knowledge of the mysteries of this busy insect. A few years ago the masses would have thought it miraculous to have seen bees handled with impunity, as we now handle them; and yet we are not satisfied with our progress, nor should we be, so long as we can save the life of another colony, or cause them to produce another pound of honey.

While the winter of 1880-81 will long be remembered by the apiarist, the question that arises is, have we been benefited by our experience to the extent that we may reasonably expect to avoid another such disaster? If we have not, we have not taken the lesson that nature has offered us.

While the old elm-peeler hog could bury himself in the ground beside a log, and winter through, without much comfort to himself or profit to his owner, the improved Berkshire or Poland China cannot stand such treatment, but needs to be well housed, to give his owner a good profit, and the same may be said of all the domestic animals, and the honey bee is not an exception to this rule.

We no longer expect to get profit from the bee in the old log hive, left standing exposed to the cold north-westers without protection, no more than we would expect that the old brindle cow, that has to shelter under the leeward of a rail fence, would give profit to her owner.

Then, as true humanitarians, let us investigate in the light of science and experience, and especially the subject of wintering, for this is the reef that we have wrecked upon. In wintering, some attribute their success to ventilation, others to the extracting of bad, unripe honey, others to the temperature, and so on. Now, without entering into a discussion of this subject in this address, I prefer to leave the discussion of this subject, with all others, to this convention, merely hinting at a few subjects which I may think of importance to bee-keepers. Some of the things necessary in wintering, in my experience, are a hive of proper size, contracted according to the number of bees, and plenty of good, ripe honey, or sugar, with good ventilation, and well protected from the cold. But the question arises, what is the proper size of the hive, how shall we ventilate, and how shall we protect from the cold? with numerous other questions which this Association may discuss with profit.

I would advise all beginners to study the physiology and habits of the bee, which may be done by reading Quinby, Langstroth or Cook; and without the study of some such standard work on bees, our bee periodicals must sound much like the German does to the man who cannot speak German; but if he has studied all that has been written on the bee, he none the less needs to read some good bee paper to keep up with the progress of the age.

We cannot expect every family to take interest enough in bees to supply themselves with honey, when they, with plenty of garden room, fail to

exert that energy necessary to raise the common vegetables to supply the family table, and are satisfied to live on "hog and hominy the year round." The race is not won by the sluggard, but by him who is ever on the alert and ready to exert both his physical and mental powers.

While much has been accomplished by our leading apiarists in the science of bee-keeping, there are hundreds of smaller lights scattered throughout the country with a few colonies, with their untiring zeal and energy, who have added much to the knowledge and progress that have been made in bee-keeping; and the result is, that the sweet-silvered voice of the patent hive vender with his moth-trap is no longer heeded in our land, except by him who reads not.

In our discussions I have observed that we are more inclined to speak of our success than our failures, when often our best lessons are from our failures; then let us not fail to give our experience, wherein we have failed, that others may benefit thereby.

In my observations, there is no industry in this country in which there has been more progress made in a decade, both scientifically and practically, where the product comes from the soil; and if a majority of our citizens could be induced to keep a few colonies of bees, there would be much wealth gathered annually which now is lost, to say nothing of the effects that a good dish of honey has upon the family, socially, for we are all prone to get a little sour at times, and need sweetening up, and if it could not be done with honey, a few stings would make us forget ourselves for the time being.

I would call to remembrance the death of the Rev. J. C. Bellman, the first president elect of this Association, hoping that this Society will remember him with appropriate resolutions.

While the Agricultural College of Indiana, Purdue, is experimenting with all the domestic animals, and has so far omitted the bee, I think it would be well for this Association to call the attention of the Board to the fact.

For the financial condition of the Association I refer you to the report of your treasurer, Mrs. E. Stout. And for the general work of the Association to the report of your secretary, Frank L. Dougherty, who has labored industriously for the up-building of the Association.

There has been a move in some of the other industrial associations of this State, as well as this one, to obtain an appropriation from the State, that they might be able to give their discussions to the masses, fresh from their meetings. I would, therefore, recommend co-operation with these societies in an effort to procure such an appropriation.

In conclusion, let me congratulate this Association on the great stride that has been made toward the improvement of the honey bee, and while we have not been able yet to breed them without stinging, or with a tongue long enough to reach the honey

in the red clover on our deep rich soils, we have lessened the propensity to sting, and are increasing the pasture by the cultivation of many honey-producing plants; and, considering the time since the experiments commenced, I think the improvements in the bee have been equal to the improvements in any of the domestic animals.

The several particulars mentioned in the president's address were discussed at some length, eliciting many facts of direct interest to those present.

A committee, consisting of Mrs. Cass Robbins, Dr. J. H. O'Rear and J. M. Robinson, reported a series of appropriate resolutions on the death of the Rev. J. C. Bellman, a former president of the Society.

The subject of "Dividing, or Natural Increase" was again taken up, the subject leading to a discussion of the best plan of handling natural swarms. The prevailing opinion seemed to favor a basket or box in which to secure swarms that have settled.

Mr. Muth described a device which he had seen in use at Mr. Hill's, near Cincinnati, consisting of an oblong, perforated box, which could be quickly adjusted to a pole. He thought any shaped box, holding not more than a half-bushel, bored full of one-half inch holes, and leaving both ends open, would answer all practical purposes.

The opinion of the majority seemed to be that, in divisions of all kinds, the main object should be to keep all of the old bees together, that the largest amount of honey might be secured. The meeting adjourned for supper.

The evening session was called to order promptly at 7:30. The first question being that of "Wintering."

Dr. O'Rear was a strong advocate of indoor wintering, preferring a house above ground.

Mr. Shaw also sided with the Doctor, believing that the difference in the amount of stores consumed would more than compensate for the trouble and cost of the building.

Mr. Muth, Mr. Dougherty, and many others had wintered on the summer stands for years successfully. They thought that, while indoor wintering had some advantages in the Northern States, it was not preferable in this latitude.

Providing pasturage for the bees was discussed with an interest which bodes good for the future honey crops of Indiana. The value of all the honey-producing plants which grow in our climate was fully discussed. Alsike and sweet clover (*mellilot*) being the favorites.

Mr. Thompson, president of the State Dairymen's Association, said he was not a bee-keeper, but the thorough discussion he had just heard called up a new line of thought to him. The dairymen are directly interested in the clover, and he thought there would be no need of scattering the seed in the fence corners and waste places, as some member had sug-

gested, but each could greatly assist the other in the planting process, for, quoting Prof. Cook, "happily, civilization is opposed to selfishness."

Mr. Mason had not succeeded in getting a good start with mellilot; thought alsike preferable.

Mr. Leaming had visited Mr. Salisbury, in Illinois, who had many acres of it sown, and who pronounced it a decided success, after trial on a large scale.

The hour having become quite late, the meeting adjourned until the morning.

The second day's meeting was called to order promptly at 9 a. m., with increased attendance. The election of officers became the order of business. All the old officers were re-elected for another term, as follows: For President, Hon. I. N. Cotton, Traders' Point; Secretary, Frank L. Dougherty; Treasurer, Mrs. E. Stout, both of Indianapolis. On motion of Dr. O'Rear, a committee was appointed to confer with the State Board of Agriculture, on the subject of larger premiums and better accommodations for the bee-keeping interest.

A communication from Dr. A. B. Mason, Toledo, Ohio, in reference to the Tri-State Fair, of Ohio, Michigan and Indiana, was referred to a special committee, consisting of Messrs. Muth, Davis and Johnson. They recommended the sending of President Cotton as a delegate to said Fair, with power to act for the Society, in the best possible manner, for the interest of the bee-keepers.

Prof. Cox, formerly State Geologist, now of California, entertained the Society with a description of bee-keeping in that State. Prof. Collett also spoke a few minutes, in his happy style, of the instruction and moral influences of the honey bee. The rest of the morning session was consumed in discussing minor subjects connected with the business.

The afternoon session opened with a discussion of the merits of comb foundation, the secretary describing the particulars of its manufacture in different forms, including the wired frames as made on the Given press, samples of which he had present.

Gov. Porter being present, was called on to address the Society, which he did. He complimented the Society on its increased attendance each year, and on the intelligent manner of its discussions; he referred to his former meeting with the Society, and of the general information he had gained during his short stay. He was greatly interested in these industrial meetings of the several State societies, and believed that they should have all the encouragement possible, as they were destined to place our State in the very front rank of industrial States. He spoke of the great improvement in the several industries; thought the Legislature should make a small allowance for each society to enable it to send our reports of the proceedings of the meetings to all parts of the State, so as to place the knowledge of the specialist into the hands of those who are

unable to attend the regular meetings.

Mr. Muth informally replied to the Governor, showing that a growing demand for liquid honey was springing up—being now largely consumed in manufacturing. Among manufacturers using honey are the pork packers, for sugar-cured hams; tobaccoists, bakers, confectioners, manufacturers of printers' rollers, etc.

I. N. Cotton, Dr. O'Rear, J. Kinney, Mrs. Robbins and Mrs. Stout were appointed delegates to the North American Bee-Keepers' Society, with instructions to ask the Society to hold its next session in Indianapolis.

After some appropriate resolutions for favors conferred on the Society, the meeting adjourned to the call of the Executive Committee.—*Indiana Farmer.*

Best Way to Use Small Sections.

DR. G. L. TINKER.

That the readers of the BEE JOURNAL may know why it is proposed to have the new small sections only $1\frac{3}{8}$ inches thick, it may be well to explain how they are to be used.

I think that every bee-keeper can see that it would be a great advantage if the sections could be set down at once upon the brood frames so that the passage ways would be continuous into the sections. With broad frames or racks holding the 2-inch sections it is necessary to raise them at least $\frac{1}{4}$ inch above the brood frames, in order to admit the bees into all the passage ways between the sections. This $\frac{1}{4}$ inch space I believe to be a hindrance to the bees entering the sections and affords a place for the bees to build comb, which often interferes in lifting out the frames. It is also no little trouble to cut away these bits of comb after the section cases are taken off. Some colonies are worse than others about building comb in this space and can hardly be induced to go above it, into the sections, to work. If the passage ways between the brood frames and the sections were continuous, there is no doubt but that it would facilitate the bees in their work and result in a larger surplus.

Now, with a thin section to be used with or without separators, this space is unnecessary and the section case or rack can be set upon the brood frames so that all of the passage ways will be continuous. If a rack is used it may contain 36 to 40 sections, according to the length of the brood frame; 36 can be used on 9 Gallup frames, and 40 upon 8 Langstroth. After the bees have one rack of sections partly filled it may be lifted off and an empty rack of sections put on. The upper rack is then slid over the other one, endwise, and no bees need be killed. By tiering up in this manner, 120 half-pound sections can be used at once to advantage.

If wood separators 1-16 inches thick be used between sections $1\frac{3}{8}$ inches thick, 9 brood frames can be evenly spaced 17-16 inches from center to

center, in a hive just 13 inches wide, so that when the rack of sections is slid over the frames, the spaces will all be continuous. But if the section be $1\frac{1}{2}$ inches thick, the frames would have to be spaced 19-16 inches from center to center, but the hive would have to be just 14 inches wide to hold 9 frames where 10 are ordinarily used. This would be spacing the frames too far apart, and I think would not work satisfactorily. Hence, if the sections are to be set upon the frames in the manner here proposed, the section ought not to be over $1\frac{3}{8}$ inches thick. If used without separators, a section $3\frac{5}{8} \times 3\frac{5}{8} \times 1\frac{3}{8}$ will hold just one-half pound. If separators be used, the size may be $3\frac{3}{4} \times 3\frac{3}{4} \times 1\frac{3}{8}$, which will hold very near one-half pound.

To prevent the killing of bees, the brood frames must be brought up on a level with the top of the body of the hive, so that the rack of sections can be slid over the frames endwise. As I have used a similar arrangement to the above, I can speak from experience as to its practicability. There may be some danger of the queen moving up into the section department, but I do not think it would often occur, especially where the deeper frames are used.

Since most bee-keepers will only use a few of the half-pound sections, the first season, on trial, it would not be much trouble to prepare a few hives and fixtures for the purpose, making, of course, the hives to fit the frames in use, and then, sometime in May, set the frames and bees from some of the old hives into them.

For the American Bee Journal.

The Forncrook Patent Section.

M. M. BALDRIDGE.

I have received Mr. Forncrook's catalogue for 1883, in which I find the following language: "We intend to prosecute manufacturers who infringe upon our rights to manufacture a one-piece section of any description." Also the following: "We do not intend to molest bee-keepers for using the one-piece sections they may have bought of other parties previous to Dec. 1, 1881, but caution them against buying any not bearing our stamp." The latter quotation is equivalent to saying that bee-keepers will be prosecuted for infringement of the Forncrook patent for using one-piece sections "of any description" made by outside parties since Dec. 1, 1881.

As the above is misleading, forbearance any longer to dissect the Forncrook patent, ceases to be a virtue.

Having had more or less experience during the past 25 years in overhauling specifications and claims on "patent hives," it enables me to understand the points in Mr. Forncrook's patent. Having in my possession the Forncrook specifications and claims, I will now give the latter, which are as follows: I claim "as a new article of manufacture, a blank for honey-

frames formed of a single piece of wood having transverse angular grooves *c*, longitudinal groove *d*, and recesses *b*, all arranged in the manner shown and described."

The above is what is known as a "combination" claim, being made up of parts, as follows: One (1) strip of wood; three (3) transverse angular grooves; one (1) longitudinal groove; and two (2) recesses or passage ways for the bees, with both ends of the strip "dentated" so they will "interlock when brought together." The specifications and drawings must always be referred to, to get at a proper understanding of the claims and what is meant by the following words: "All arranged in the manner shown and described." The following engraving illustrates the entire claim:

Now, it must be apparent that, the omission of any of the parts enumerated destroys the "combination," and renders the patent null and void.

I will now introduce three illustrations, as follows:

As none of the above sections possess all the parts of the "combination," they evidently do not infringe upon the Forncrook patent.

And now let me suggest another destructive element, to-wit: The omission of simply the "longitudinal groove!" In other words, the section can be made all in one piece, with both ends dentated, with the 3 transverse angular grooves, and with tops and bottoms narrower than the sides, and still not infringe the Forncrook patent! And why not omit the "longitudinal groove," inasmuch as the section is just as good without it? For my own use I always omit said groove; in fact, I would as soon use a latitudinal groove as a "longitudinal one!"

As a rule, any "combination" patent can be easily evaded; in other words, it is not very difficult to drive a "span of horses" or a "yoke of oxen" right through one! I have yet to find a "combination" patent, on bee-hives, that cannot be evaded, and still retain all the essentials. The Langstroth patent was the most difficult to evade, but even that could be done and still make the hive very practical.

Now, if Mr. Forncrook has as good sense as I give him credit for, he will never prosecute the makers, vendors, or users of the one-piece section for infringement, so long as they omit any of the parts of his "combination," as indicated in his patent, and as set forth in this article.

For one, I would like to hear from Mr. Forncrook through the BEE JOURNAL in reply to my analysis of

his patent. I have no desire to mislead the readers of the BEE JOURNAL, nor have I any desire to injure Mr. Fornerook, financially or otherwise. My only desire is simply to state facts as I find them, and without fear or favor from any one.

St. Charles, Ill.

[The BEE JOURNAL believes in the old maxim: "Right wrongs no one." In dealing out "exact justice to all," it will neither countenance *extortion* on the part of an inventor, nor allow an "*exaction*" of a legitimate patent, in order to *defraud* its owner, without an earnest protest. To do so, would only impede "progress" and discourage "invention." The one-piece section now enjoys a well-earned popularity, and, as its inventor has spent much time and money in bringing it to its present state of perfection—is he not entitled to a *reasonable* reward? We believe that all right-minded persons will cheerfully assent to this, but will not, willingly, submit to *extortion* on the one hand, nor countenance *dishonesty* on the other.—ED.]

For the American Bee Journal.

My Bee Cellar and Management.

REUBEN HAVENS.

My cellar is 22x44 feet, divided into three rooms. The first room is but half underground, which I use for a shop and store room. There is a large out-door opening into this room; also one opening from the kitchen. The other rooms have heavy stone walls, plastered; it is also lathed and plastered overhead. It has a tile running around the bottom, just inside the wall, cement floor; and two four light 12x14 windows in each room. My bee room is the one farthest from the outer door.

On the north side, I have a 4-inch pipe 8 feet long; on the south side, a 6-inch pipe with a cross, or T pipe, on the outside for ventilation. Upper ventilation is given by a flue running to the bottom of the cellar; pipe hole near the ceiling. If the room becomes too warm, which it often does, I ventilate by opening the outside door, and letting the fresh air pass in through the other two rooms. In this way I can keep an even temperature.

In putting the bees away for winter, I place the hives on racks; the first tier 2 feet from the floor, and every hive is placed so that it can be moved without disturbing the others. After placing the hives, I remove the tops and leave no covering, except the quilts.

By the way, I bought a lot of hives last summer with enamel cloth covers, which I left on, when I put them into winter quarters, and on examination, a few days since, I found the moisture had condensed on the quilts and run down through the combs and out at the entrance of the hives, causing the

bees to become very uneasy. I immediately stripped off the enamel covers and replaced them with covers made of worn ingrain carpet. This is the best material for covers that I have ever used. If worn, then make them double. I think keeping an even temperature and good upper ventilation, are the main things in successful wintering.

There seems to be quite a difference of opinion in regard to the right temperature, varying from 32 to 44 degrees. I find when the temperature gets above 40 degrees, the bees become very uneasy.

Onarga, Ill., Jan. 18, 1883.

For the American Bee Journal.

Sections, Separators, Apprentices, &c.

JAMES HEDDON, 173-500.

After reading a few more thoughts from others, I wish to say a little more about the half-pound sections. On page 8, Mr. Benedict, in his second paragraph, says "a prime colony will produce $\frac{1}{3}$ more honey in one-pound than in half-pound sections." *Why* they will, he does not say; and, *why* they will *not*, is too long a story to tell here.

Now, I am quite sure that if I could have Mr. Benedict in my yard three days next summer, I could convince him that more comb honey can be procured in pound or half-pound sections, than in any larger receptacles. If he is correct, then I am wrong, and half-pound sections will soon be among the "things that were." I shall use a few of them next season. I think that extra cost and manipulation is the main objection to their use. But, as I can use them on the same hives with my pounds, and in the same size crate, I shall feel bound to make some comprehensive tests, regarding them, next season.

On page 18, the editor tells Dr. Tinker that this section "requires extra capping, and comb foundation; perhaps too much to be profitable." My experience with combs, down as thin as $\frac{7}{8}$ in. has convinced me that (some how or other) the bees finish sealing the thinnest combs first, and apparently easiest. Also, I have demonstrated that the more foundation I can crowd into use, the better for my yield of comb honey, to an amount far exceeding the extra cost.

Dr. Miller (one of those who "get there") can imagine the queen making her home and "nest" in the sections, if they are so thin as would be needed for half-pounds, of 4 $\frac{1}{4}$ x4 $\frac{1}{4}$ square. I would tell the Doctor to go ahead, and fear no brood in the sections, of any thickness; but I object to such thin comb, for reasons I have already given on pages 5 and 27. I wish I was as sure of a good crop in 1883, as that, with any thing like reasonable management, we shall have no brood troubles.

Let me say to Dr. L. C. Whiting (see page 42) that if he will try the process of putting up honey in large frames, and then cutting up and fitting into sections to be properly fin-

ished up by the bees, he will want to forget the day the thought first entered his mind. Try it, Doctor, (just a little) and report.

Mr. Caldwell (p. 8) says, that in some seasons bees were reluctant to work among separators, and wonders if as much honey will be stored with, as without them, and yet the same article is headed "Separators a Necessity." Dr. Miller and Capt. Scudder, (page 20) are of the same opinion. I have no fears about straight combs, but two bee-keepers (who also "get there," and in whom I place great confidence,) assure me that my fears of their damaging my crop, is groundless. One of them presents the best arguments I have ever heard, and presents a little different manner of their use and manipulation; and, while I am putting considerable money into such experiments, as I deem essential to the proper instruction of my class of students for 1883, I shall add \$10 for tin for separators, and make one more test on a broad and improved scale. If I find my former views changed in any way, I shall be only too glad to tell all about it. If not, I shall consider a \$10 box of tin, a solid perch upon which to crow, "I—told—you—so."

On page 36 Dr. Miller tells us some thing about "Who should Keep Bees." When I read that, "I threw up my hat," and shouted, "My wife asked 'What is up?' I replied, 'A pen picture of real life; an article worth twice the price of the BEE JOURNAL for a year, to every reader; an antidote for Blessed Bees.'" Every one should read that article and not get discouraged, for the article is the best of encouragement to all who should embark in the business, and who understand the article rightly.

On page 6, Dr. Besse points out "another advance step," as one very desirable to be taken. That there is a great demand for the services of competent apiarists, I very well know, from the numerous applications which come to me. All are willing to pay high wages, if they can get the right sort of a man. The Doctor maps out a plan by which he thinks the right man can be detected from the wrong one. From all that I know of the apian student-apprentice business, together with diplomas and seals of presidents, secretaries and whole societies, committees and all included—all these seals and signatures, with all the expense and trouble of the red tape circumlocution, mentioned by the correspondent, would only throw suspicion upon any one who might apply to me. I should say, Where did you *practice* honey-producing? With Mr. G. T. Success. Good. What recommendations can you give? This paper. It reads: "The bearer, Mr. Henry Goodwin, has spent five months in my apiary of 200 colonies, having passed through the season's operations, from unpacking the bees in the spring to repacking them for winter quarters. I have found Mr. G. a young man of integrity and tact. He has studied the theory of apiculture under my supervision, and has been with me in practice

through spring preparation, queen-rearing, surplus storing of both comb and extracted honey, transferring natural and artificial swarming, etc., together with all the mechanical labors connected with the production and fitting for market of 20,000 pounds of surplus honey. While he has yet more to learn, I consider him fully competent to *successfully* manage an apiary of 100 colonies, spring count. Signed, "Get There Success."

The above is the sort of diploma I want.

Is this the firm of Capable & Rich? Yes sir. You have advertised for a salesman, I believe? Yes sir; we need one badly. I am here to make application for the place. What testimonials of character and ability can you give? He takes out a document, covered with the seals and signatures of all the officers and committees of a popular commercial college, avowing that the bearer, "Studious S. Slow-motion" is everything that a college professor imagines a young commercial man ought to be. It is all lined and trimmed with red tape. The proprietor drops his head, looks disappointed, and says, I will consult our head salesman, and give you an answer in a moment. John: here is a young man seeking the place, where we so much need help, and here is his testimonials. John reads a little ways, and says: "There is no use to try any more of those commercial college graduates; they usually have less than one-fourth of the native tact of a boot-black, and they have it all to learn after they get here. We don't want any more stupid apprentices; we want an experienced man, one who has had practice, and is not all theory."

About such dialogues as this occur daily in our large cities, I am credibly informed. I like the Doctor's ideas, all but the diplomas and signatures, which I think entirely useless. The results would show that a bee-man is a bee-man "for a' that, and a' that," and that a failure could pass the examination, get the signatures and yet be a failure "for a' that."

On page 43, Mr. Chas. Follett gets up "another step higher." I like the solid metallic ring of "his" short reply. I believe he has reached a point where he can defy failure; but his article gives conclusive evidence of at least two points: first, that, if after 3 years of apprenticeship, he blundered to a loss of \$300 to \$500, either he did not become a student as well as an apprentice, during the time, or else his teacher was incompetent. Secondly, in any case, it shows the great value of experience before we invest our capital.

In chemistry, 3-7 of A. and 4-7 of B, mixed together, make a healthful nutritive food, but 3-7 of B, and 4-7 of A are together a deadly poison; so apicultural success will be reached only by a proper mixture of thought and labor. The apiarist, in the backwoods, with no teacher, no reading matter, no thought to clash with and sharpen his own, will fail; so the commercial student, who is buried under a mass of books and teachers,

having no store or fabric of merchandise with which to practice, soon forgets even how to "swap jack-knives." Any apiarist, to do justice to student apprentices, must invest a few hundred dollars in experimental fixtures; the extra labor, thus incurred, the students will perform, and should, in justice to them, have that extra labor supplied them.

Mr. Follett will think five months (which constitutes a season here, as we unpack about May 1st, and repack the last days of September) rather a short time to become proficient in the art of honey production. My limited experience with students proves that this five months of study and practical experiment puts them on the right track, and prepares their minds for receiving all new truths right end foremost. All of my students, who have commenced bee-keeping, are to-day succeeding; two will begin in apiaries of mine, on shares, this spring. My faith is thus great; with these five months instruction, any reasonably apt man can have of me an apiary of 100 colonies on shares, a position which will pay him more than high wages, one year with another, and one in which he can "blunder" and finish his education at my expense. Of course I will direct the operations. I shall get better results than to sell the bees. It will not take five months to convince him that comb-honey production, when properly pursued, pays much better than extracted.

Dowagiac, Mich., Jan. 22, 1883.

For the American Bee Journal.

Small Sections, Best Bees, etc.

DR. J. R. BAKER.

We are a great people, but, withal, a little eccentric; and I think I never saw the latter characteristic crop out more prominently—at least in bee-keeping circles—than in the half-pound section business.

Because two or three honey-producers, who believe in the grand principle of ever marching forward, and who like to experiment and indulge in novelties, put a few half-pound sections of honey, in nice shape, on the market, and found a good sale for it, why, about half of the bee-keeping fraternity seem to have gotten half-pound section on the brain!

It seems to me that Capt. L. H. Scudder, of New Boston, Ill., Mr. F. C. Benedict, Dr. Miller, James Heddon and others, in the week or two last past have taken the sensible view of the matter, as expressed in the BEE JOURNAL, and now comes, in the last issue of the BEE JOURNAL, Mr. Frank L. Ripley, of Boston, Mass., with a clincher, which it is hoped will act as a sedative on the over-anxious victims of the half-pound section craze.

It is contrary to good judgment to expect the half-pound sections to ever become universally in demand; for, there are a few who always seem to think that acting ridiculously is the displaying of wisdom, the majority of honey consumers will prefer to buy

just as little wood as possible, at from 20 to 30 cts. per pound. The Irishman said that he wanted just as much whisky as possible and as little quinine in his prescription as would make it legal. So the most of the honey buyers will want as much honey as possible and as little wood for the money.

In view of this fact I think the majority of bee-keepers had better stick to the one and two-pound sections, for awhile yet, at least. I know one that will, at all events.

I have looked on with a good deal of interest in the discussion as to the merits of the different varieties of bees, that has been indulged in with so much ability and warmth by some of the apicultural gladiators in our country; and the result of the discussion, to my mind, has been a complete routing of the three-band advocates. While the thorough-bred Italians, with their beautiful yellow bands, are, as a rule, very docile, and always pleasing to the eye of one who loves the beautiful, I am fully persuaded that for honey-gathering the dark-colored (or hybrids, if you please) are much superior, as a general thing, to the golden beauties. While this seems to be the experience of a majority of our experienced apiarists, it is *most decidedly* mine. That this is true, I very much regret, for if there is anything that I love to look upon, it is a colony of beautiful yellow bees.

Now, while what I have said as to the superiority of the dark bees as honey-gatherers, I am much inclined to think there is a remedy for it, and that is, in the selection of the good honey-gatherers from among the yellow bees as breeders, and the merciless beheading of every queen whose progeny prove to be indifferent workers. No difference, if her bees have forty gold bands, let her go to the "block," unless the bees are good for business. I am quite certain that it is the in-breeding of the American Italians for bands, instead of for *workers*, that has wrought the mischief in the ranks of yellow bees. If the yellow bees are expected to keep abreast of their more homely and irascible neighbors as *business* insects, they must be judiciously selected.

There are good workers among the most beautiful yellow bees. I know, and if the breeders of these would breed from nothing but such, there would soon be less to say about the yellow bees being inferior to the dark as workers. The trouble has been, that if a queen breeder of Italians had a golden queen whose progeny were a beautiful yellow, she was valued very highly, without reference to the business qualities of her bees at all. All this must be speedily changed, if the golden-banded beauties are to hold a place in the affections of our best apiarists.

Let some man well-fitted for queen-breeding give us a good strain of golden Italians and he shall be called blessed, by one lover of the beautiful, at least.

There is no better locality for honey production than near the upper Mississippi. I believe the honey reports

of the country will prove this assertion. But while this is true, I am a victim of chronic, malarial poisoning; and I am fully persuaded that I must find another field. I must go to some point where malaria is a stranger; but, while this is true, I must also go where bees do well. To rob me of the pleasure of keeping bees, on quite an extensive scale, would be to deprive me of a world of pleasure, to say nothing about the pecuniary consideration. I flatter myself that I am a successful bee-master; and I am looking for a pleasant locality, good for bees, and entirely free from bilious difficulties.

Dr. F. A. Grove, of Kirksville, Mo., seems to have the right notion about keeping bees for profit. He keeps bees, poultry, a little other good stock, raises a little small fruit and cultivates a good vegetable garden. I am quite certain this is better for the majority of bee-keepers than to keep bees alone. My advice to all beginners is: go slowly, and learn as you go. He who rushes into a business up to his eyes, of which he knows comparatively nothing, is apt to get his profits all on the debtor side.

Keithsburg, Ill., Jan. 20, 1883.

SELECTIONS FROM OUR LETTER BOX

Swarms Went to the Woods.

I have 27 colonies; 19 on the summer stands and 8 in the cellar. I wish to try both plans, and report in spring. They gave me a very poor yield last year, owing to the cold late spring. During August, I was in the West, and lost 6 or 8 swarms. I will try and do better during the coming season, if I can. J. BRISTOL.

Greenwood, Ind., Jan. 20, 1883.

The 2-lb. Sections Good Enough.

We have been very much interested in the half-pound section question, but have decided to adhere to our 2-lb. sections, for the present at least. Taking everything into consideration, the change does not promise to terminate in a success financially.

GREINER BROS.

Naples, N. Y., Jan. 19, 1883.

My Way of Wintering Bees.

I always winter my bees on the summer stands. This is my third winter, and I have not lost any yet. My plan of preparation is as follows: After the boxes are taken off, I put on Mr. Hill's device; then cover the frames with a piece of as thin factory as I can get (large enough to come outside of the hive, after the cap is on). On the top of this, I place a cushion, 4 inches thick, filled with chaff, and give plenty of ventilation above the cushion. They are on their summer stands, and have a good roof for shade, supported at each corner by a small post, the outer case is easy put on. For the case, I take best canvas, 40 inches wide; this is wide

enough for 2, stretch and tack this down tightly, and it will turn rain or wind as good as boards. It is much cheaper and more quickly done. They get all the fresh air they need at the entrance. As it is the same size as in the summer, with a small tube or box from the entrance to the outer case, the bees can fly whenever a warm day comes, although mine have not had a flight since about Nov. 15th; they are taking a good rest, to awake during the first warm days of spring to come forth with the early flowers, with their glad hum, ready for another year's labor.

S. C. FREDERICK.

Coal Vale, Kansas, Jan. 22, 1883.

Statistics—Planting for Honey, etc.

I have been trying to ascertain the number of bees in Lucas Co., Iowa, this winter, and this will show how well I have succeeded. I have found 28 men that keep bees; they represent 661 colonies; 72 of them have bees in box hives and log gums; the remainder in frame hives, 90 per cent. of the latter in Langstroth hives; 6 of the latter take a bee paper and represent 448 colonies of bees, and have taken the past season between 9 and 10 tons of honey. I have made out my report, the best I could, and sent to Dr. C. C. Miller. Bees are wintering well, so far; there is one thing that bothers me a little. In 3 or 4 of my hives I find thin honey running out at the entrance. What is the reason? Mice cannot get in. Tell me the cause and remedy. It is too cold to open the hives to see. I sowed 3 lbs. of catnip seed, last fall, along the creek banks, in ditches and waste places. Will it pay? Will sweet clover come up this spring, if sowed in February?

WM. MALONE.

Oakley, Iowa, Jan. 16, 1883.

[The "thin honey running out at the entrance" is probably condensed moisture that could not escape at the top. In running down over the combs it came in contact with honey and became *sweet water*. This will make the bees uneasy, and during the first warm weather you should place some good absorbent over the frames. This is about all you can do, until an examination can be made in the spring.

Of course "it will pay" to plant forage for bees. Sweet clover planted on the snow in early spring will do well; freezing the seed is beneficial to it.—ED.]

My Years' Work.

I commenced the spring of 1882 with 2 colonies of bees and increased to 12 strong colonies, and got 150 lbs. of comb honey, in 1-pound sections, and 150 lbs. of extracted honey. I sold the comb honey for 20 cts. per lb.; the extracted for 15 cts. at home. I use the Langstroth hive, of my own make. My bees are wintering on the summer stands, packed in clover chaff.

GEORGE N. MARSH.

Huntley Grove, Ill., Jan. 24, 1883.

Do the Drones Accompany a Swarm?

I have just finished reading the pamphlet entitled "Dzierzon's Theory." I appreciate the theory of Dzierzon (and indorse it) for its valuable instructions, but I want to ask whether drones (male bees) issue with the first swarm in "natural swarming?"

Dr. H. R. DONN.

Worden, Ill., Jan. 19, 1883.

[This is governed by the circumstances. Usually the old queen and workers, old and young, compose the swarm, and therefore they have no need of drones. In such cases the drones remain in the hive to fertilize the young queen, whose "wedding flight" occurs in a few days after the swarm leaves. If the old queen is unable to fly (from her wings being clipped, or some other cause), then the bees, after returning to the hive, will sometimes take the young queen with them, when they issue again. Then drones, being necessary, will also go with the swarm.—ED.]

Duty on Beeswax.

It is within my knowledge that in view of the great rise in price of wax in the United States that arrangements were being made by a large firm of merchants in London, to place considerable quantities of beeswax on the American markets. The only obstacle, I believe, was the duty.

THOMAS B. BLOW.

Welwyn, England, Jan. 10, 1883.

[As wax is so much used in Europe, we did not think that there would be a chance of getting any there.—ED.]

A Continuous Blizzard.

We are having a blizzard here at present; averaging 10° below zero, during the past few days; but my bees are in a sawdust bee-house and doing well. We have had continuous sleighing since the last of November. No practical apiarist can afford to do without the AMERICAN BEE JOURNAL.

A. BURRILL.

Cuba, N. Y., Jan. 24, 1883.

Half-pound Sections.

I am sorry to see the half-pound sections favorably spoken of by any one. There may be a demand for them in some places, but I am quite sure that in the Western States they are too small. J. J. TUCKER.

Arrow Rock, Mo., Jan. 20, 1883.

Trying Theories on Wintering Bees.

Saturday night it thawed and rained a little with the mercury at 38° F., but early on Sunday morning the wind changed to the west, blowing a perfect gale, which has been kept up ever since. The mercury dropped below zero and this morning it was 12° below. Since Nov. 11 the mercury has not been above 42°, so that the bees have had no chance to fly. All seem to be wintering well so far, but if our winter

keeps on till April, as it has begun, all will know of how much value their pet theories are, regarding wintering bees.

G. M. DOOLITTLE.
Borodino, N. Y., Jan. 23, 1883.

Bees Quiet Yet.

I fear that unless the bees have a slight before long they will not winter well, although many of them are quiet yet.

FAY KENNEL.
South Gates, N. Y., Jan. 20, 1883.

Best Hive for Comb Honey.

DEAR EDITOR:—As a new subscriber to your very valuable and instructive BEE JOURNAL, I want more light. Will you please give your opinion which is the best form of frame—the deep or shallow, when we have in view to obtain the most comb honey only? My purpose is not to get extracted honey, but the most profit from the use of sections.

H. B. HAMMON.
Bristolville, O., Jan. 22, 1883.

[We prefer the Langstroth hive and frame for all purposes, and more especially is it well-adapted to the production of combhoney. With a shallow frame, the bees are more easily induced to work in sections, over the frames. For side storing, the Langstroth broad frame is just the right size to hold 8 one-pound sections. Other sizes can be used, just as well as in any other hive.—ED.]

Bees in the Cellar Wintering Well.

Messrs. Crocker & Blake, of Boston, have kindly sent me a half-pound section measuring $3\frac{1}{2} \times 3\frac{1}{2} \times 1\frac{1}{2}$. I'm afraid Mr. Heddon is mistaken. I suspect there will always be a larger market for one-pounds than for the half-pounds; and if the latter is over-stocked, the one-pounds will bring the highest price. Bees are wintering nicely in the cellar, so far.

C. C. MILLER, 174-202.
Marengo, Ill., Jan. 9, 1883.

Bees Doing Exceedingly Well.

Bees did remarkably well last year: one man got about 13,000 lbs. from 100 colonies in the spring, and increased to 200; another got 375 lbs. from 2 colonies in the spring, and increased to 19; another told me he had cleared \$800 on 60 colonies, in honey alone.

B. T. BALDWIN.
Oskaloosa, Iowa, Jan. 22, 1883.

Poor Season for Honey.

We have thus far had quite a pleasant winter, although it is pretty cold, and growing colder, with a steadily increasing depth of snow. Last season was a very poor one here for honey; there was an abundance of clover, but the weather was too cold for it to secrete honey. I obtained only about 3,000 lbs. of comb honey from 90 colonies, and increased them to 106. My bees are wintering nicely, so far; I winter them in a large cellar

under the dwelling house; the cellar is very damp, having in it a large open cistern, but I keep it well ventilated. Bees went into winter quarters pretty light in stores, therefore, I look for a favorable spring for them. Perhaps I shall be disappointed, but I shall make observations in this direction. Last winter they were *unusually* heavy, and the spring was one of the coldest and most backward I ever saw.

B. T. DAVENPORT.
Auroraville, Wis., Jan. 20, 1883.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., January 29, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. here.
BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, on arrival; dark and off colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@8c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@15c. on arrival.
BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—January month, and still there is a large surplus of comb honey on the market. Prices are weak owing to large offerings, and anxiety on the part of shippers and holders here to realize on the product. Extracted honey is steady, but the demand is light.

We quote: white comb honey, in 1@2 lb. sections, 17@18c. Dark comb honey, hardly any demand. It is held at 12@15c. Extracted—White brings from 10@10c.; dark, 8@9c.; kegs, half-barrels and casks bring about same price.

BEESWAX—Yellow, 30@32c.; dark, 27@28c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Nothing of consequence is at present doing. There is no special inquiry, and no selling pressure, unless it is on off qualities.

White comb, 17@20c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9c.; dark and candied, 7@8c.

BEESWAX—We quote 25@28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Strained, at 6@7c., was salable—one lot of 17 bbls. bringing inside figure; but comb, very dull at 10c. to 18c.; and extracted do., 8@9c.

BEESWAX—Steady; choice, 27@27c.; dark, 20@22c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Has changed in price a very little, we find it necessary to sell all grades about 1 cent per lb. less. Best white, in 1 lb. sections, 20@21c. per pound; in 2 lb. sections, 18@20c. Extracted is very dull indeed, hardly any sale.

BEESWAX—Scarce, 28@30c.
A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—There is very little stock here and the movement only of a peddling character.

We quote: White clover, first quality, 1 lb. boxes, 24@25c. fair to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c.

BEESWAX—The supply is not large and prices firmly held for prime lots.

Western pure, 30@32c.; southern, pure, 31@33c.
D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Moving Bees in Winter.

As we have quite a number of queries about moving bees, and the best method of preparing them for shipment, we will give some directions, as we have often done before, but which seem not to have been seen by those who now send in questions on the subject. Mr. T. F. Kinsel, Shiloh, O., writes thus:

I am wintering my bees in the cellar. I expect to sell some, and move 6 to 8 miles soon, if it can be done with safety. How shall I proceed? We have good sleighing, and they could be drawn on a sled. Would it be better to wait until spring? Ought they to be placed in a cellar after removing, etc.? Will the unavoidable jolting in moving hurt them?

We cannot advise the removal of bees, in any manner, during a season, when they cannot have a good flight immediately afterward. We would much prefer running the risk of breaking down combs, in the early spring, over rough roads, than to risk their disturbance in winter. It *might* do to move them on a sled over the snow, but all the chances are against it.

Here is another letter, asking similar questions, from Mr. M. E. Buck, McLean, Ill.:

Bees have done well here during the past summer. The spring was very cold and backward. I commenced with 23 colonies, spring count, and increased to 50, by natural swarming. My bees are the natives, mixed somewhat with the Italians. I am using the Mitchell hive. I have taken 1,600 pounds of comb honey; a good part of it in one-pound sections. The greatest yield from one colony was 90 pounds in one-pound sections. For wintering, I am trying the plan of covering my hives over with hay or

straw, on the summer stands. I want to ship my bees to Kansas. Would it do to ship by freight? Which is the best way to pack or fix them, where there are 50 or 75 colonies put on one car? Would it do to pack or heap them together? Is Kansas a good place for bees? I intend to go there and go into the business.

Some parts of Kansas are good for bees, as shown by reports from some bee-keepers there. The best time for shipping bees is in April, or quite early in May, before the combs are too heavy with brood; but with proper care in preparing them and ordinary usage in handling, they may be shipped at any time with comparative safety, except in cold weather, if properly prepared for the journey.

The first work of preparation is to go through the hives and extract about all the uncapped honey, as the least daubing will prove fatal to the bees; then procure a block 1 inch square, and as long as the hive is wide, in this cut notches and tack in the bottom of the hive, in which to place the frames to keep them steady; now select the new combs and those heavy with brood or sealed honey, secure them well in the frames with strip-binders, and place in the hive; tack the ends of the frames firmly to the rabbets on which they rest; dip the blanket in clean water, lightly wring, fold about six thicknesses, and lay on the front ends of the frames.

If the hive has no portico, leave off the cover, and use wire cloth instead, nailing on top of that, three one-inch strips, two inches wide—one across the center, the others across each end, to insure ventilation when piled on each other. Now tack wire cloth over the entrance, and your bees are ready for shipment.

If the hive has a portico, prepare in the same manner as above, except to bore a $1\frac{1}{2}$ inch hole in each side of the brood chamber, and also in the cover, which will be used in place of the wire cloth over the frames; the holes

to be covered inside and outside with wire cloth, to admit of ventilation. Leave the entrance open the full size, but cover the entire portico securely with wire cloth, leaving free access to it from the interior of the hive; care must be taken, however, to bore a $1\frac{1}{2}$ inch hole under the roof-board of the portico, and left open, to allow free ingress to the interior of the hive, as the entrance beneath may become choked up, and the cluster of bees, with the queen, die of starvation through inability to get at the honey in the hive.

Hives made with porticoes are much better for shipping bees, for it allows them to drag out the dead, cleanse the hive, and, to a great extent, prevent dysentery. Prepared in this manner, full colonies may be shipped at all seasons, from May 1st until Aug. 10th, with perfect success. They should be sent by freight, and loaded with the frames running lengthwise of the car—the end of the frames pointing towards the engine. If packed in the car the other way, the “bumping” may break the frames down. Old and tough combs are best for shipping. Express charges are too high, usually, except for short distances.

Mr. G. Damkohler, Clarence, Mo., remarks as follows:

I intend to move to Florida in March, and as it may be quite cold here at that time, will you please to give some directions, in the BEE JOURNAL, how to prepare bees for shipment in winter? I heard, a few days ago, that a whole car load of bees passed through here, on their way South. Perhaps you know something about that shipment.

The trouble will be to prepare them for the journey so early. In Missouri there may be some warm days when you can do so, but here in the North, it would be too much to expect. To the foregoing general directions for shipping bees, we direct attention.

Here is another letter of inquiry from Mr. T. Thurlow, Lancaster, Pa.,

who asks about moving bees by rail in winter. He says:

I am going into Maryland in February, a journey of 200 miles. My 14 colonies of bees are in double-walled hives, with chaff cushions on top. The question with me is, whether to leave the cushions on, or to fasten down the frames, take the cushions off and give them the whole cap to roam around in, with holes through the cap, covered with wire cloth. Which?

The answer given to the preceding questions will apply to this. We do not think it reasonable to expect weather warm enough to prepare bees for shipment during *this* month. If the weather was warm enough not to chill the brood, if they have it, it would be best to give the bees the cap to cluster in; especially would it be desirable, if the combs should break down, to give them space to cluster in, and thus, perhaps, save the entire colony.

The Sting of the Honey Bee.

A correspondent has sent us the following descriptive article on the above subject, taken from an English periodical entitled *Good Words*:

If we press the abdomen of a bee, so as to cause the sting to protrude, we should naturally think that the sharp, dark-colored instrument was

that, if the savages had possessed microscopes, we should certainly have thought that they borrowed the idea of the barb from the insect. What we see with the unaided eye is simply the sheath of the sting. Many savages poison their spears and arrows, and here also they have been anticipated by the insect. But the sting is infinitely superior to the arrow poison. No poison that has yet been made, not even the terrible wourali, or curare, as it is sometimes called, can retain its strength after long exposure to air. The upas poison of Borneo, for example, loses its potency in two or three hours. But the venom of the sting is never exposed to the air at all. It is secreted by two long, thread-like glands, not nearly so thick as a human hair, and is then received into a little bag at the base of the sting. When the insect uses its weapon it contracts the abdomen, thereby forcing the sting out and compressing the venom-bag.

By the force of the stroke which drives the sting into the foe, its base is pressed against the venom-bag and a small amount of poison driven into the wound. The barbed weapon cannot be withdrawn, and the whole apparatus of sting, poison-bag and glands is torn out of the insect, thereby causing its ultimate death.

The Honey Market in England.

The following letter will be very interesting to our readers:

There is not much English honey to be found on the market, even the largest producers, the most prominent bee-keepers, have had none to sell this winter. Mr. Cowan wrote me the other day, saying he had some in 1 lb. jars to offer at 1s. 3d. (30 cts.) per pound. English comb honey in sections of 1 lb. to 2 lb., bring from 1s. 6d. (36 cts.) to 2s. (48 cts.) per pound; but, even at these prices, it is very seldom 1,000 lbs. can be found in one parcel, or in even one neighborhood, so that if a firm confine themselves to English honey alone, they must, of necessity, be content with very small operations.

West India, Mexican, Chilian, etc., honey, in barrels containing from 250 lbs. and upwards to 600 lbs., have been selling at auction, upon Mincing Lane, at from 28s. per 112 lbs. (6 cts. per pound) to 46s. 8d. (10 cts. per pound). A parcel of 73 barrels of about 600 lbs. each, were shipped from Tuxpam, Mexico, to New Orleans, thence to Liverpool, and from Liverpool to London, by rail, consigned to Messrs. Geo. Hooper & Co., upon whom the shipper drew a 90 days draft through Messrs. Baring Bros., at the rate of 25s. per cwt., about 5½ cts. per pound, but the honey was simply filthy with dead bees, etc., so that Messrs. Hooper very properly declined to accept the draft. Messrs. Baring Bros. have, through their brokers, been hawking this honey about, and would, I think, be glad to close it out at 5 cts. This class of cheap, foreign honey has rather im-

proved the market for finer grades, because buyers are getting so that they will not have the poor grades, at any price.

California honey has been in good demand; one sale, a large one, of Wilkins' honey, sold in Liverpool at 18 cts. per pound. There never was but one parcel of California comb honey brought over here, and that was a parcel of 100 cases by Messrs. Thurber & Co., but they sent it all back to New York two years ago, because it was badly broken, and had to be repacked, which only could be done there. We would gladly pay cash for the grade known in California as "Extra C.," 20 cts. per pound, net here. California strained, in 5-quart tins, and barrels of about 250 pounds, bring from 10 to 18 cts. per pound.

There has been but very little Western honey imported here, as yet. Nor has there been any honey without comb imported from the Eastern States. Before Christmas, we had about 1,200 cases in all; 700 from Boston, at 23 cts. per pound; 450 from Philadelphia, at 22 cts. per pound; and 50 from New York at 21 cts. per pound. It was all very satisfactory, and arrived safe and sound. We are now entirely out of the glass-sided boxes, and could sell many more cases, at from 28 to 30 cts. per pound, if they were to be had. We have been obliged to go to Hamburg, and buy from those fellows you have seen go around with a wooden tray upon their head, selling honey. We buy it from them in straw supers, and cut out the combs, for repacking in jars.

I wish you would come over next summer. We are to have the International Fisheries Exhibition here under the patronage of the Queen and the presidency of the Prince of Wales, and at Amsterdam, they will have a great International Exhibition under the patronage of the King of the Netherlands. At the latter there is to be a great honey show from all parts of Europe. You must come; you have been appointed one of the judges, Mr. Editor.

Now when you come, this time, you can arrange it to make some money. Bring over a consignment of comb honey, any shape, so it is white and nice. I will sell it all for you, so that you can take the money back in your pocket, and at a good profit.

W. M. HOGG.
London, England, Jan. 11, 1883.

We should be delighted to do as Mr. Hogg suggests, but with a Weekly Bee Paper on our hands, it is impossible. Our last visit cost us over a thousand dollars, in money, besides months of valuable time, but we have the consolation of knowing that it was well spent in developing the market for American honey; now, some one else may go and reap the harvest. We would, were it possible.

Attention is called to our new and liberal advertising rates for 1883.

The Sting of the Bee.

the sting itself. This, however, is not the case. The real sting is a very slender instrument, nearly transparent, keenly pointed, and armed on one edge with a row of barbs. So exactly does the sting resemble the many-barbed arrow of certain savage tribes

Bee-Keeping in Egypt.

During the past year Egypt has been brought into prominent notice by the events of the war. It is one of the oldest countries, and is the "bridge" of three continents, Asia and Africa it links by land, and by the Suez Canal it lets European commerce through to the Indies and Australia. In it, the haughty Pharaohs have erected proud structures to perpetuate their names and deeds throughout all ages.

But what a sad contrast, between the land in its era of monuments, and Egypt of to-day! How fallen, since the time that Joseph sat on its throne next to Pharaoh. What shadows have cast their gloom over the land since that time! Perpetually under the domination of foreigners: the Assyrian, the Persian, the Macedonian, the Roman, the Arabian, the Georgian and Tartar slaves, and the indolent Turk. But its fertilizing waters still are pouring into the many tributaries of the White and the Blue rivers, to be wafted down and deposited by the Nile, in Lower Egypt. The once fertile valley of the Pharaohs, with its 4,000 towns and cities, can yet produce as perfect a flora, when properly irrigated. It is still the Eden of flowers. A correspondent, who has visited that country, says:

As a commercial country, it possesses many advantages: bees and honey still forming an important article of trade. The verdure of Upper Egypt generally withers at the end of four or five months, and commences earlier than in Lower Egypt. In consequence of this, the Lower Egyptians collect the bees of several villages, in large boats; each hive having a mark by which the owner recognizes it, they commence the gradual ascent of the Nile, stopping whenever they come to a region of herbage and flowers. At break of day the bees issue in thousands; and busily collect the sweets of the flowers, which are spread in luxuriant profusion around them, returning to their hives laden with honey, and issuing forth again in quest of more, several times during the course of a day. Thus, for three or four months, they travel in a land of flowers, and are brought back to the place whence they started, with the delicious product of the sweet orange-flowers, which perfume the Said, the roses of Faioum, and the jessamines of Arabia.

Nature still possesses her charms in the historic Valley of the Nile, which has always been the great magnet of the human race, as the land of natural resources. But the inhabitants are poor indeed—no better than slaves. The correspondent adds:

They not allowed to make use of corn and rice for food, since all that they can raise is demanded by their masters. Indian millet, forming a coarse bread, water, raw onions, sometimes a little honey, cheese, dates, and sour milk, form their constant, and only food. A shirt of coarse linen, dyed blue, and a black cloak, a cloth bonnet, with a long red handkerchief rolled around it, form their costume.

Such a population, dwelling in miserable hovels, moving among the monuments of ancient grandeur, awaken in the mind of the stranger a painful interest. The bees and their owners, like the pyramids, defy modern civilization, and, for management, as relentlessly point us back three thousand years ago. With their clay cylinders for hives, their keepers but mock at modern bee culture, and laugh to scorn the progressive ideas of the nineteenth century.

Judicious Use of Comb Foundation.

Mr. Sylvester Marshall, of Pratt's Fork., O., propounds the following questions:

Which is the best kind of comb foundation to use for getting extracted honey—drone or worker? How thick should it be to obtain the best results?

Drone comb foundation has been used, to some extent, but now it is entirely discarded; the worker-cell comb foundation answers every purpose, and as drone cells in a hive is a temptation to drone-rearing when such are not wanted, it is preferable not to have it there for any purpose.

Experience has demonstrated that comb foundation, for the brood chamber and extracting, should be about $4\frac{1}{2}$ feet to the pound, with a thin base and heavy side walls. This is the most desirable for economy in the use of wax and rapidity of comb building by the bees.

Considering the start given to a colony of bees, by a judicious use of comb foundation, the certainty of having the combs all built straight, the ease with which the number of drones produced by a colony may be controlled, no one can justly intimate that we are not making prodigious strides in placing bee-culture among the scientific and profitable occupations of the present progressive age.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Letter from Switzerland.

The talented and gentlemanly editor of the *Bulletin D'Apiculture*, published at Nyon, Switzerland, Mons. Bertrand, writes us as follows:

I have sown at Nyon, on some land I purchased, $2\frac{1}{2}$ acres of Bokhara clover seed, and nearly as much at my Mountain Apiary; so you see that I am following your advice in the editorial articles in the BEE JOURNAL. We could not do without your able JOURNAL, and this is the universal opinion.

We are sorry to learn that our friend and co-laborer has been unwell from excessive labor and cares, and hope he may speedily be restored to his accustomed vigor and health.

We have received the initial copy of the *New England Apiarian*, published by W. W. Merrill, Mechanic Falls, Maine. In it we are assured that the publisher "is in no way connected with a former short-lived journal published in that place." Had this announcement not been made, it would generally have been considered but a revival of that paper which a year ago issued one number, but never succeeded in publishing another. As several of the Maine bee-keepers seem to be giving it their influence, we hope it may succeed. It seems to have progressive ideas, and the BEE JOURNAL wishes it prosperity, and extends its of welcome to the infant.

The January number of the *Kansas Bee-Keeper* is on our desk, in an enlarged form. The "Question Department" is in charge of Mr. James Heddon, of Michigan, and Dr. Howard, of Texas, has become assistant editor.

How Birds are Deceived.—The woodpeckers in Norway bore into telegraph posts, being misled by the humming sound, to the belief that there are insects in the wood. The bears sometimes scratch away the heaps of stones put to support the pole, thinking that the noise proceeds from a nest of bees.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on *at least one new* subscription with your own? Our premium, "Bees and Honey," in cloth, for one *new* subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

For the American Bee Journal.

Profitable Use of Foundation, or Old Combs, when the Supply is Limited.

G. M. DOOLITTLE.

It often happens that the apiarist wishes to give each swarm, when hived, a start, in the way of frames filled with comb or foundation, but does not have enough of such to give a *hive full* to all the swarms he expects will issue, hence he wishes to give four or five frames to each, or near that amount. To this end he places his four or five frames of comb in the center of the hive, and fills out each side with empty frames, and places his swarms upon them.

As the queen has plenty of room to lay in these combs without the bees building more, she goes to work depositing eggs. As honey is coming in at the time, the bees must have a place to store it, so they fill the empty frames with stores, which are always of the drone size of cells, the same as they would build if hived in an empty hive with an old unprolific queen. Hence, the apiarist becomes disgusted with the use of old combs, and declares that they are of no use to swarms, as a colony not helped at all will accomplish more than does the swarm he has tried to help.

This was about the decision I came to, when first trying to use a limited number of combs for a swarm. Therefore, I decided to use a hive full of comb, or none at all. I soon found that these swarms hived on full sets of combs, so far surpassed those not helped at all, that I wished for a way to help all alike, if possible. I had also noted that by the use of the division board I could generally get from four to five frames filled with nice straight worker comb, after which I would get more or less drone comb built by a swarm having no help at all by way of frames of comb.

I studied on this matter during the winter, and the result was that the next season found me placing ten frames, each having a nice starter of worker comb along the top bar, in each hive; I placed a division board in the center, thus leaving five frames on each side. This division board did not come quite to the bottom of the hive, but allowed room for the bees to pass under it, as they desired. Into these hives I placed my swarms, and in whichever side the queen chanced to go, there the bees commenced work. As fast as the bees could build comb it was filled with eggs, hence, nothing but worker comb was built.

After the swarm had been hived 48 hours, I put on the boxes or sections, which were immediately taken possession of, thus securing the five frames filled entirely of worker comb; for if any drone comb was built, it was in the sections. As soon as these

five frames were filled (which was readily ascertained by the bees commencing work in the vacant side of the hive), the frames in the vacant side of the hive were taken out and the division board moved to side of hive.

I next spread these combs apart, and put in each alternate space a frame of comb, thus securing a full hive of nice, straight worker comb. As I used only nine frames to the hive, this gave the swarm four empty combs.

I thus secured two objects, a hive full of all worker comb, and the bees taking possession of the sections in the shortest possible time. I have been so well pleased with it, that I have used it for years, and find it works equally well in using comb foundation where the apiarist does not feel able to buy enough to have a full hive of it for each swarm.

Central Kansas Convention.

On Thursday, Jan. 11, 1883, some of the bee-keepers of Kansas, met at Manhattan, to form an Association. Many were prevented from attending on account of the severe cold weather. Mr. Marlatt was called upon to preside; and on motion, the following persons were appointed a committee on permanent organization, with instructions to report at 2 p. m. on Saturday, Jan. 20, 1883, viz.: R. Corbett, Ed. Kimball and M. D. Waters.

On Saturday, Jan. 20, another meeting was held, and the report of the committee was made by its secretary, M. D. Waters, who presented a Constitution and By-Laws of the Central Kansas Bee-Keepers' Association, which was, on motion, adopted.

An election of officers for the ensuing year was then held, with the following result:

President, D. B. Himes.

Vice-President, E. Kimball.

Secretary, Thomas Bassler.

Treasurer, R. Corbett.

After some interesting discussions on several points of progressive bee-culture, the Association adjourned to meet at the call of the secretary.

THOMAS BASSLER, Sec.

For the American Bee Journal.

Chaff Hives and Upward Ventilation.

T. C. DAVIS.

It gave me much pleasure to see an article from the pen of Mr. Doolittle, on page 52 of the BEE JOURNAL, on this subject, because I am fully convinced that our safe wintering problem is to be solved by the chaff hive and its proper ventilation.

In the winter of 1880 and 1881, I had five of the A. I. Root chaff hives, and five others, of my own make, of the same size as the Simplicity, with fixed bottoms, and the ends double, with 3 inches of space filled with chaff. They had also double stories, put on the same as the Simplicity.

From the 20th of June until the first week in October of 1880, I was in Europe, and had no one to feed the bees during the dry spell we had in the early fall, so when they were examined in October, I found them rather weak and deficient in young bees. I had nothing to do but to pack them for winter, the best way I could, on their summer stands, in those hives. They were all put on four frames, in the middle of the hives, and the sides filled with division boards and chaff. Passages were made in all the combs, and passage ways were provided between the frames and the coverings, by laying small sticks across the frames. The coverings were made of an old ingrain carpet, that was once a good and thick one. Above that there were six inches of loose oat chaff, and a good chaff cushion, so that the upper stories were nearly full with chaff.

Four of those in the Root chaff-hives, wintered excellently, and came out, in the spring, strong and healthy without any help, except about a pound of candy made of sugar and flour, that was laid on the frames about the middle of March. In the other Root hive, they dwindled badly. They were uneasy and flew out continually, when the weather was not intensely cold, and died on the snow. It puzzled me greatly to know why this colony acted so different to the rest. I thought they were all packed exactly the same, and the entrances of all were closed the same, to about four inches.

After many fruitless examinations, I noticed that the carpet on this one, was not exactly the same as on the others. The other four were cut exactly the size of the hives, and they had raveled some at the ends. After putting them close to the front parts of the hives, they were rather short at the other ends, but not short enough to let the chaff fall in. The carpet on this one was an inch longer than the hive, and both ends were closed tight. When I found this difference, the carpet was turned back about $\frac{1}{4}$ of an inch, and a little straw laid on the opening under the chaff. From that moment the bees became more easy, and did not fly out as before. They came out all right, but I had to put them on two frames and helped them with some brood from other hives.

When the other five hives were examined, I found the carpets packed close, the same as the last mentioned, and a considerable dampness in the hives. I turned these carpets back, also, and filled up as before. The entrances of these were not more than an inch, and they were enlarged to 4 inches at once. They showed some signs of dysentery, and they dwindled some, but after this, the hives dried out some, and all came out strong and in good condition by the end of May.

During the winter of 1881-82 I had 15 of Root's chaff hives, and 3 of the others, packed in the same way, with the carpets turned back about $\frac{1}{4}$ of an inch at the back part, and the entrances of all the chaff hives left wide open. They all came out in splendid condition.

This winter, I have the 15 chaff hives, and 2 of the others, on their

summer stands, packed exactly in the same way, except that they are all on 5 frames, on account of their being very strong last fall. They are doing well so far, and there is not a particle of frost inside the entrances of any of them, in spite of the "cold snaps" we are having. I have also 8 others in a small, dark and well-ventilated cellar, doing well so far.

I never tried coverings of porous cloth over them, and it seems to me that Mr. Doolittle's experience speaks against it. But I believe that my experience with a warm quilt, or a carpet over them, proves that no upper ventilation will not do. It may be all right as long as the weather keeps really cold; but in my neighborhood, where we have sudden changes, and spells of moderate weather, in the coldest winters, it will not do. I do not know but $\frac{1}{8}$ of an inch of an opening to the chaff at the back end of the hive, would be sufficient, but I am confident $\frac{1}{4}$ of an inch is plenty.

In this locality, bad honey in the fall, and pollen in the hives, does not trouble me in the least, and if I have all the Root chaff hives I need, and have my bees packed as I said, I have no fear of loss. The difference I find between the Root chaff hive and those I make myself for wintering, is, mine are more apt to get damp in the bottom, when the others are always dry, and that of course is greatly in their favor. There may be other hives quite as well as they are, but I have not seen them yet.

Pittsburgh, Pa., Jan. 26, 1883.

For the American Bee Journal.

Lorain Co., O., Convention.

The bee-keepers of Lorain County, Ohio, met in the Probate Court Room of the Court House at Elyria, Dec. 20, at 10 a. m. and organized a society under the name of The Lorain Co. Bee-Keepers' Association.

A constitution was adopted, similar to one in general use by other societies of the kind, with the following officers: President, Joseph Hudson; Vice President, C. D. Bennett; Secretary, O. J. Terrell; Treasurer, M. R. Bennett.

T. C. Crilly and C. D. Bennett were appointed a committee on statistics. Adjourned till 1:30 p. m.

President Hudson called the meeting to order at 1:30 p. m.

Mr. Jump was called for but did not respond.

O. J. Terrell, being called for, made a few remarks in favor of organized work; he also spoke of the manner in which his bees were packed for the winter, namely, in clamps, with clover haff; also, that he would rather have our inches of clover chaff than ten inches of any other packing he could think of.

B. F. Worcester described a bee-house which he built, years ago, at the East, which wintered bees successfully, although the winters were very severe. It was made with very tight single walls, with ground floor, and ventilation at top and bottom. He

considered the ventilation a very essential thing.

Mr. Tompkins said he weighed his bees in the fall and again in the spring, and the average loss per colony was about 7 pounds. One small nucleus, fed 20 pounds of granulated sugar-syrup, had gained 5 pounds.

The merits and demerits of the chaff hive were quite thoroughly discussed, the majority being in favor of the chaff hives.

The committee on statistics submitted the following table:

Apiaries.	No. of Colonies in Spring.	No. of Colonies in Fall.	Comb Honey, pounds.	Extracted H. pounds.
1	60	75	1,500
2	20	26	425
3	69	100	3,450
4	11	25	400
5	20	30	400
6	12	18	300
7	5	13	400
8	13	19	240
9	7	12	300
10	11	15	200	600
11	21	47	500
12	60	73	2,000	1,000
13	15	22	225	325
14	3	8	250
15	1	2
16	5	10	180
17	14	24	568	220
18	5	11	165
19	6	9	250
20	9	14	400
21	1	3
22	1	3	50
23	7	14	120
24	2	2	50
25	1	3	45
26	4	6	50	300
27	100	125	4,000
28	7	11	60
29	13	18	822	250
30	6	11	154
31	20	20	500
32	5	13	800
33	5	15	200
34	1	2
35	8	8	75
36	13	7	278
37	79	75	3,300	200
38	2	6	140
39	4	4	90
40	22	49	112	1,400
	668	918	21,784	5,510

The question being asked whether it would pay to plant for honey alone. Mr. W. C. Suttill replied that it would not, but there were plenty of crops that would yield both honey and good hay. He preferred alsike clover to anything he had tried.

L. L. Sears claimed something good for mignonette. It lasted till cold weather and was a wonderful plant to secrete honey.

J. E. Squires said, in speaking of the different races of bees, that he did not want anything to do with the Cyprians. Had had one large colony, and

they were so cross that he gave the queen away, and divided the colony into four small nuclei, giving them Italian queens, which he claims are good enough for him.

The question was asked by a member, if it paid to keep bees? This brought forth a lively discussion, and it was thoroughly proved by several that bees, rightly managed, did pay.

Some effort was made to establish uniform prices for honey, but this was a vexatious question and will be more thoroughly discussed at the next meeting.

Mr. Geo. H. Purple exhibited a novel machine, which he makes use of, in taking a swarm of bees from a tree. The machine is so arranged that he can hang in it a frame of brood comb, so that the bees readily take to it.

The Association passed a resolution of thanks to the Probate Judge, for the use of his court room, and also to the county papers, which so kindly inserted the notice of the meeting in their columns the previous week.

On motion of B. F. Worcester, the meeting adjourned to the second Tuesday in March, 1883.

O. J. TERRELL, Sec

For the American Bee Journal.

Wintering Bees in the South.

FRANK THIAVILLE.

Wintering bees in the South is no trouble, if the bees are in proper condition, with plenty of bees and honey. A populous colony that has 25 pounds of honey on the 1st of November, will winter well on the summer stand, and be ready for the honey season when it comes.

An ordinary colony may winter well with 8 pounds of honey, provided the honey season opens early, say by March 1; but if the spring is cool and backward, they will perish, unless fed. During the period of repose, bees consume an average of 2 pounds of honey per month; but when breeding time comes, they require at first 2 pounds, then 3 and 4 pounds per week, according to the strength of the colony, and the quantity of brood that is being reared.

A critical time for our bees is when the honey season opens early, and is cut off, by frost and cool weather; our hives being then full of bees and brood, they must have honey, or the barrel of sugar must be ready.

Colonies well supplied with honey will remain quiet at home, and there is no spring dwindling; but, if they have not honey enough, they will fly out during the cool days, get chilled and perish, and the colony will dwindle, and even, if it can pull through, it is worthless for the season.

In the winter of 1880-81, no bees perished on the summer stands, so long as they had honey; but the spring was cool and backward, and a great many perished by the last of March, and first part of April, just at the eve of the honey season.

We are located between 34° and 35° north latitude. In the winter of 1880-81, the thermometer seldom went

down to zero; it was several times at 3° and 5° above at daybreak, but at noon it had raised to 29°. It was, for several weeks, at 10° and 12° above at daybreak, and 30° and 40° at noon; and about every week or ten days the bees had a flight.

Last winter, the thermometer did not sink much below 25° above zero at night, and at noon 60° to 75°.

Last Sunday, Jan. 21, was the coldest of the season; at daybreak it was at 9° above zero; and at noon 30°. Yesterday it was moderating; at daybreak 16°; and at noon 45°. To-day is pleasant, and bees fly if they want to.

In cool, hard winters I put my bees into a bee-house, or pack them with leaves and straw, for about 6 weeks, from Dec. 10 to the middle or last of January, and it saves honey. There is very little breeding at this date. This is an indication that we will have a late spring.

Forest City, Ark., Jan. 23, 1883.

For the American Bee Journal.

How to Market Honey.

G. W. DEMAREE.

Mr. James Heddon "publicly invites" me to write an article on the above subject. Of course he does not expect to be benefited by it himself, because he has already "got there." It is presumable, however, that he wishes to "prove me" as to whether I know anything about practical matters pertaining to bee culture. I write, then, in the hope of benefiting those who have had trouble to establish a market for their honey. I believe that there are many such, judging from the private inquiries I have received in the past.

Before I take up the subject, however, I wish to say that the article of Mr. Heddon, which contains the invitation before mentioned, though purporting to be a "clear" statement of his "position," shows "confusion worse confounded." His "second" proposition which, in fact, is the text of his discourse, is replete with error, and is marvelously superficial, when viewed from a historical and scientific standpoint. Of our native bees, uncontaminated with the blood of other races, I have noticed at least four varieties. While, of the Italian, the variety is "legion," hence, to confine the "long" or "shorter-bodied" specimens of the Italian to any imaginary variety of the race, is not only an error, but is an egregious blunder. The truth is, the long, slender-bodied specimens of the Italian race are superior to the short, thick-bodied specimens, no matter whether they are "dark" or "light." As far as my observation extends, the length of the body is in no way influenced by the color.

Mr. H. has not attempted to controvert a single important proposition that I have laid down, except in the way of *argumentum ad crumenam*—argument to the purse, "bread and butter." Is life a great "tread wheel," with its perpetual creaking under an unceasing tread? Even

though the inevitable trough be filled with bread and butter, such a life is the meanest bondage that ever bowed the neck of man. If all of us should write on "bread and butter," who would be left to do the scientific thinking and writing?

In the "long ago" I kept some bees to supply our table with honey; and, even then, when I knew but little about bees, I loved to watch them as they bore their precious loads of nectar to their home—"sweet home." After the modern system of bee-keeping became a reality, I purchased some Italian bees and began to study their habits and natural history. Time went on, and my bees multiplied under good management, and soon we had honey for our own use and plenty to spare, and of this, I would send around to our neighbors, each a nice package, every once in a while. When a person wanted a "bucket" of honey I sold it to him.

I bought an extractor and produced both comb and extracted honey. I felt some anxiety to introduce the extracted article, but the chances looked bad at the start. My customers, when they came for honey, would say, "I want honey just like that I got from you last." I would show them the one-and-a-half-pound sections, and show them the article of extracted, and explain it all to them. It was all "wonderful and nice," but they must have it just like that they got from me before. Very well, then, I would say, just leave your buckets here and I will fill them in a few days. To fill these orders my nice section honey was cut out and the buckets were filled without bruising the combs more than could be avoided, and then the very best quality of extracted honey was poured into the buckets till every nook and corner was full. Put up in this way, a three gallon bucket will hold 35 pounds of our best white clover honey. These packages gave perfect satisfaction, and when these customers returned for more honey, they were pressing in their requests that the honey must be just like what they had been getting from me.

On one occasion, a good customer sent in 4 three-gallon buckets, and ordered them filled with honey "like he had been getting from me." At a venture, I filled 3 of them in the usual way, and the other I filled with the very best article of extracted white clover, so thick that it would nearly "stand alone." Being a pleasant fellow to deal with, he said nothing and paid the bill—20 odd dollars. The next season, his buckets came back with an order for 1 or 2 hundred pounds of honey like "that one bucket that had no wax in it." He had "put that bucket full aside till winter, and it was simply splendid, there were no pieces of hard wax to get into his teeth;" others were induced to try it, and it "took" every time.

Well, by and by, my little honey house became stored with more honey than my good little home market demanded, and I began to look out for a city market. I put some samples of nice section in the "show case," in a

fancy grocery, in Shelbyville, and they stood there several weeks. They were "very nice," but nobody seemed to think that honey, in that shape, was made to eat. I then corresponded with a firm in Louisville, proposing to send them some sample crates of sections; also some extracted honey; explaining the whole thing to them, and setting a price on the honey, warranting the honey to be just as I described it, or they might return it, at my expense. They wrote me to send it on, and I sent them one crate of 32 sections and 2 sixty-pound kegs of extracted honey. In a few days I received a check for the price of the honey, and an order for more. I now had an outlet for all the crop that was not taken by the home market.

It is unnecessary to pursue the subject further, all large things have small beginnings. It takes skill and patience to create a demand for honey, in any locality, where the business is new, but when once the trade is established, it is as easy to sell honey as any other product for consumption. I insist that our local markets should be cultivated to the fullest extent, for we thereby lessen the competition in the city markets. The subject, pertaining to the "size of the packages," is interesting; but to create a demand for honey as daily food in the stead of the vile table syrups on the markets, is a matter of more interest.

Christiansburg, Ky.

Nebraska State Convention.

The Nebraska State Bee-Keepers' Association met at the Court House in Wahoo, and was called to order by T. L. VonDorn, President, on Jan. 11, 1883. Quite a large number of the members from various portions of the State were present.

Secretary Hawley read his annual report, which on motion was received and placed on file. The treasurer, F. F. Caldwell, made his annual report, which on motion was referred to a committee on finance, consisting of Messrs. Trester, Rose and Jordan.

The bill of the Allen Printing Co., of Omaha, for 250 copies of the By-laws of the Association, amounting to \$7.50, was allowed, and an order drawn on the treasurer for the amount.

Quite a number joined the Association, and members paid their dues.

The election of officers was postponed until 9 a. m. to-morrow.

On motion, the president was instructed to appoint a committee of one on statistics, and M. L. Trester, of Lincoln, was appointed as such committee.

Mr. Corbett, of Plattsmouth, called for a report from persons who had cultivated forage for bees. This led to a spirited and lively discussion regarding the successful growing of clovers and tame grasses in Nebraska, which was of great interest to farmers and stock raisers, as well as apiarists.

Mr. Stark, of Beatrice, said: I have sowed about 40 acres of red clover and it is doing well, and I have a good pasture. I plowed the ground, harrowed it until well pulverized, then sowed

the seed and rolled it. It blooms well and the bees work on it well. I pasture the field with cattle, and do not think there is any question but what clover can be grown successfully in Nebraska. I also sowed two acres of sweet clover, six pounds to the acre; seed cost 30 cents per pound.

Mr. Muir, of Brownsville, said: I have been in Nebraska since 1856, and my experience and observation lead me to conclude that the new soil of Nebraska will not produce good clover and tame grasses, but that as it becomes cultivated, and is cropped for several years, it will produce good tame grasses. As the soil becomes cultivated, it becomes more solid, the clover does not so easily winter-kill, and grows more thrifty; I consider white clover the best forage for bees.

Mr. Fletcher, of Wahoo, said he thought there was no doubt about raising clover in this State. He sowed 10 pounds of seed, two years ago, and now had 20 acres of good clover. He pastured the field, and thought that was the best way to insure a growth.

Dr. McAllister, of Columbus, said: A few years ago, white clover was sown in a few of the lots of that city, and was now spreading all over the streets and adjoining lots. He considered sweet clover the best honey-producing plant.

Mr. Myers, of Bellevue, said: Two years ago I sowed 20 pounds of clover seed on prairie sod, and on the north slope of a hill, the soil was new and had never been cultivated, and I have had a good field of clover there ever since; I think white clover would grow anywhere, if hogs were kept out of it.

Mr. Trester said: I have sown tame grasses and clover in Nebraska every year since 1862, and have never failed of getting a good crop but once, and then it was poor seed. My plan is to harrow the ground down smooth, then sow three or four kinds of tame grass seed mixed, and in about double the quantity that is recommended by the seed men. Then I harrow it thoroughly, and, when the first crop is ripe, I mow it and leave it upon the ground, and I have no trouble in getting the ground matted with clover by the second year. I have sown on sod and on cultivated land, and I have no doubt but what tame grasses of all kinds can be successfully grown in this State.

Mr. Rouse, of Wahoo, said: Three years ago there was a pasture lot near my residence seeded to red clover, and, in a little, white clover appeared with it, and now it had nearly run the red out. I think all that is needed, to get forage for our bees, is to scatter white clover seed. I find that it even spreads on the prairie, where it has not ever been broken. I think that white clover always secretes honey in moist seasons, but in dry seasons does not.

G. M. Hawley said: I sowed white clover, seven years ago, and it winter-killed. Some has since been sown in the cemetery lot, which is growing and spreading; I think that, as the country becomes older and more cultivated, tame grasses will do better.

Mr. Corbett, of Plattsmouth, said: I am glad to see the turn this question has taken. I think clover will grow well in Nebraska. I have always had success, even when sown on the open prairie, without any preparation whatever; I have watched it in dry seasons, and do not see that it kills out. I think white clover does best when not shaded, and if it does kill out, some winters, it will return again. I think it secretes honey only in moist seasons.

It was nearly the unanimous decision that tame grasses of all kinds would grow well in this State, and that they were profitable crops to grow, and that white and sweet clover were excellent forage plants for bees, and could be easily grown. After the close of this discussion, the Convention adjourned until 7 p. m.

The Convention was called to order by the president at 7:15 p. m. Quite a large audience of the citizens of Wahoo were present, besides the members of the Association.

Mr. T. L. Whitbeck, a member of the Saunders County Bee-Keepers' Association, made a very terse and well-timed speech of encouragement to the Convention, and the Hon. M. B. Reese, on behalf of the citizens of Wahoo and the commissioners of Saunders county, extended to the Convention a hearty welcome. Both speeches were responded to in a happy manner by the president, after which the Convention was favored with some excellent instrumental and vocal music by Miss Stocking, of Wahoo.

The question box furnished the following questions, which were discussed at length:

How far will bees go to pasturage? Various members gave it as their experience that they would go from three to seven miles, but all that was over two miles was lost labor.

How much honey will one bee gather in a life time? A bee lives but forty days, and it is estimated that one bee will gather a teaspoonful of honey during that time. Their average load is from $1\frac{1}{8}$ to 3 grains.

Is it necessary to handle queen-cells carefully? It is. They should be handled very carefully, and always kept in their original position, head down.

Why do bees of queenless hives kill their young queens? Several reasons were given by bee-keepers, but it was thought that it was only a rare occurrence that they did so.

Will Alsike clover always produce honey? Mr. Rouse said that it did not, the first year of its bloom; but Mr. Hawley and Mr. Corbett thought that it did, and they had seen their bees working on it.

When bees are wintered in a cellar, is light an injury? Mr. Hawley did not think it was, if the cellar was kept at the right temperature, which, in his opinion, was 45 degrees; but he preferred a dark cellar, because the bees kept more quiet and did not consume so much honey as in a light one. Mr. Baird and Dr. McAllister had secured the best results in dark cellars. Mr. Turney, of Cresco, wintered his

bees in a light cellar, with screen over the portico of the hive, and always with success; he preferred a light cellar. Mr. Stark thought the darker the cellar and the more quiet they were kept, the better. Mr. Whitbeck had wintered bees in cellars, for 15 years, in Wisconsin; he kept the cellar dark, but well ventilated. At 20 degrees the bees consumed more honey, but it was less work to take care of them; at 30 and 40 degrees it was more work, but they consumed less honey. The general sentiment of the Convention was in favor of wintering in dark cellars, if cellar wintering was the method adopted.

With what and how would you feed a colony of bees that have no honey? To feed with candy was decided the best.

A few moments of conversation was held, when the Convention adjourned until Friday morning, at 9 o'clock.

Convention was called to order at 9 a. m. by the president, when the following were elected officers for the ensuing year: President, T. L. Von Dorn, Omaha; Vice-President, S. L. Thomas, Plattsmouth; Secretary, M. L. Trester, Lincoln; Treasurer, F. E. Caldwell, Bellevue; Finance Committee, C. L. Speice, Dr. McAllister and J. N. Heaton, all of Columbus.

The report of the finance committee on the treasurer's report was read and adopted.

A communication from the Hon. D. H. Wheeler, President of the State Agricultural Society, was read, and in compliance with a request therein, T. L. Von Dorn and D. H. Wheeler were appointed a committee to meet with the State Agricultural Society at Lincoln, to make arrangements for exhibits and premiums on honey at the next State Fair.

It was decided that it was not best to accept the invitation extended to hold the annual meeting of the Association with the annual meeting of the State Agricultural Society.

On the question of holding the next annual meeting, Lincoln received 12 votes, and Fremont and Nebraska City 8 each. The Executive Committee will decide upon the time and place of holding it. The secretary was instructed to notify all bee-keepers in the State by postal card of the place and date when decided upon, and invite them to attend, also to issue a call for statistics from the bee-keepers of the State, said call to be published in the newspapers of the State; also to notify delinquent members of the amount of arrearage in annual dues.

The president then delivered his annual address, as follows:

PRESIDENT'S ADDRESS.

I am glad to extend to you a kindly greeting. Another year, with its cares and labors, its joys and sorrows, its attainments and its failures, has passed, and been added to that long procession of the departed ages. We have again assembled to counsel together, to exchange experiences and thoughts, to lay plans for future action. We have a common interest, an

interest in each and every one of our co-laborers, an interest in keeping up apiculture to the highest standard. Let us, therefore, be prompt to advise, ready in council to advance our cherished pursuit.

There are but few things to which I shall call your special attention this session, and these I hope will receive your careful consideration.

Owing to a season, exceptionally good, during the last half, in most of the Western States, a large surplus has been gathered, and large quantities have been thrown on the market by persons desirous of realizing at the earliest date. In consequence, prices have fallen, until they are less than the situation warrants, especially for comb honey. Added to this, there have been frequent shipments of inferior honey, and honey dew, which the shipper unable to sell at home, sends abroad to be sold at any price. This has still further demoralized trade and disgusted consumers.

With a view to freeing our markets from undue pressure, I have corresponded with several of the large dealers of this country, and also sent samples to England. The replies are here for your information. In this connection I feel warranted in saying, that if each producer would bring or send average samples of his honey to our State Fair for exhibit, that much might be done to market at that place.

I believe that a conference with the State Board of Agriculture would be of benefit to the producers and State at large. An agent for the sale of honey, in one or more of our largest towns, to retailers or jobbers, would also, in my opinion, benefit us all, in as much as one person could, by prudent measures, obtain fairer prices than a number making promiscuous sales, as is the practice now.

Next to injudicious sales, no one thing operates so much against the sale of good honey as the glucose traffic. This vile stuff, allowed by law to destroy health and sound business principles, is in one form or another upon the tables of the majority of American families. Never sold under its own name to the consumer, and ignorant of its effect upon health, its consumption is enormous. There is plenty of unimpeachable testimony, proving its total unfitness as an article of food, and I think we should leave no stone unturned to expose its true character.

I believe much can be done by our Association to place the facts before the people. But that which would deal it the deadliest blow, would be plenty of cheap wholesome honey. I am satisfied we can afford to sell our extracted honey at 10 cents per pound, and at that price it is within the reach, owing to its vastly superior flavor and sweetening qualities, of even the common laboring man. We can render no greater service to our State than to place a wholesome sweet within the reach of all its citizens.

While the exhibit at the last Fair was an improvement over all former ones, I am sorry to say it was by no means commensurate with our present status in apiculture. I am aware

that to make an exhibit, necessitates an expenditure of both time and money, yet after attending three consecutive fairs, must unhesitatingly pronounce it a paying investment for any bee-keeper who produces for sale, even for a home market. Some practical measures, looking to a more general exhibit, would be very desirable. I believe the State Board of Agriculture will do all in its power to make our exhibit a success. They certainly merit our most sincere thanks for what they have already done.

With this communication, the second term of my office as presiding officer closes. Allow me to thank you, each and every one, for the very many kind words, wishes and deeds, you have bestowed upon me. Let me assure you that I thoroughly appreciate you all, and in the years to come the remembrances of these days will always be those of sincere and unalloyed pleasure. T. L. VONDORN.

Louis Trester, a youth of about 14 years of age, read the following report of juvenile bee-keeping:

Mr. President, Ladies and Gentlemen: My Pa told me if I would write my experience in bee-keeping during the past summer, I might go to the beekeepers' meeting—so here it is: Sometime in June (about the middle, I think it was), I bargained with Pa for four frames covered with bees and filled with brood, for which I was to pay \$1.00 apiece. When I went to get them, Pa said I might take one frame with a queen-cell on, as he had several of them. I took three frames, one with a queen-cell on, and left the fourth one, thinking, perhaps something might possibly happen to my cell or queen after she hatched, and I might want another. I took the three frames and put them in a hive and closed them in as small a space as possible, by means of a division-board. All went well, notwithstanding I took a peep into the hive every day to see that nothing happened the all-important object of the hive. In due time the cell was opened and a beautiful, yellow queen came forth, but my anxiety was not over yet. I still kept peeping into the hive nearly every day, to see if my treasure, as I deemed it, was still there. About the fourth or fifth day, I looked in my hive one evening, and could not find my queen. It was late, about sundown, and I thought such a young bird as she ought to be at home. I waited until dark and then closed the front of the hive, so she would not get out earlier than I, and, in the morning, when I looked, I found her ladyship as composed as if she had always been laying, and then I got my fourth frame and commenced to build up, by adding one sheet of comb foundation at a time, putting it in the middle of the brood chamber. When honey season began I had as strong a colony of bees as my Pa had in his apiary. I bought the top story containing boxes, which cost me \$1.00, making a total cost of \$6.35 for bees, hive, foundation, section boxes, and all complete. When I put on the second story the bees seemed to have no inclination to work

in the boxes, so I put two frames with section boxes down in the brood chamber, and put four brood frames in the place the others occupied, and left them there about a week, and found that they were working in boxes both above and below; then changed all to their proper places, and then they worked readily, but after all my luck, and being a beginner in the bargain, I took from my four frames of bees, that I began with in the spring, 47 pounds of comb honey, and 53 pounds of extracted honey, leaving about 40 pounds to winter on. I sold my honey for \$15 cash, leaving me a gain of \$8.65 on \$6.35 invested.

Remember, that I still have my bees, they are yet alive. Count them at what you please, if they come through all right, in the spring, my profits will be at least double, for I have not counted my bees at all in my report.

LOUIS TRESTER.

M. L. Trester read a paper on "Single-walled vs. Double-walled hives," which contained much for interesting thought by apiarists.

Adjourned until 2 p. m.

The meeting was called to order at 2 p. m. The president read some correspondence from abroad in regard to marketing and shipping of honey.

Shall we use separators? Not, for narrow sections.

Is it more profitable to run for comb or extracted honey? Extracted.

Will chaff hives pay? A difference of opinion.

Will basswood groves grow here? Yes.

Will the Rocky Mountain bee plant grow here? It will.

Resolutions were adopted thanking the citizens of Wahoo, and the railroads for courtesies, and then the Convention adjourned.

For the American Bee Journal.

Feeders and Wired Foundation.

JAMES HEDDON.

In response to Mr. Williams' inquiry regarding my feeders, and several private inquiries in relation to wired foundation, allow me to append the following: To describe the mechanical construction of my feeders, would be simply to make confusion worse confounded. Whoever has faith in it being the best shape and style of make-up, to embrace the vital points most desirable for a bee-feeder, and who may wish to make some like it, should by all means make from a sample. Just so with any article of merchandise in the bee-keepers' line. When you get a sample, do not be too fast to make "just a little alteration," because you think such change an improvement, or may not have just the right stock to work from, and "guess it will make no difference." Recollect, that while no one claims perfection, and that you might improve any apicultural article of merchandise, you will hardly, in a single day, get ahead of one who has pondered long over, and experimented for years, perhaps, with it.

Let me illustrate. My style of hive

and surplus case is, perhaps, as simple as any form now in use. It requires more thought to reduce complication to simplicity, than *vice versa*. Several farmers about here have taken samples of my hive and lumber to the shop where I hire my lumber cut, and by the samples hired theirs gotten out in the flat, then taken home and made up. By and by, I was solicited to go and make a bid on their bees, as they were positively "going out of the business." (They were never in it much.) I was glad to buy bees "in hives just like mine." I did buy them, and I, in every case, threw away the hives. In one case, the frames also had to go. I could not use anything about the botched-up concern. One man came 30 or 40 miles and left a sample and an order for 40 hives, all to be made up by the firm who does my cutting. Happening in, one day, and seeing them all up and painted, I removed the cover, and found that the owner had left orders so to do, and they had made all of them 2 inches deeper than the frames. That bee-keeper had a bottom air chamber theory, while the real practical air chamber was "on top," just under his hat. Well, the stock boards used were hardly wide enough, so, to make sure and have this new "air chamber" fully large enough, (so that the bees could build waste comb in it) the mill men stole $\frac{1}{8}$ inch (only $\frac{1}{8}$, that is not much) from the space above the frames. This reduced that space to less than bee height, and a yoke of oxen would be needed to pull off a cover, by and by. The owner was reported afterwards, when using these hives, to call on a name "more frequent than some would advise."

Please excuse me from the futile attempt to give a description of my feeders sufficiently clear to enable one to make them accurately by it. The Patent Office experts demand comprehensive drawings or models. In the first place, he who makes only a dozen or two, makes them at a greater cost than to buy them. He who wishes to make many, for sale or otherwise, should, and can well afford to pay five prices for a sample, and then make them just like that sample. My feeder does, and I think all feeders should, embrace the following principles: It never leaks. It never daubs a bee. No robbing is caused by its use. No heat is lost. No coming in contact with the bees when refilling, or ascertaining the progress of the bees, or emptying it. It can be used equally well at the entrance, but with a feeder properly made and adjusted, "top feeding" is much to be preferred. It holds about 2 pounds, and works very well for feeding full stores for wintering. When so doing I used 4 of them (which just covered my 8 frames, Langstroth hives), and 2 fillings (16 lbs.) I find ample to last from Oct. 1st to May 1st. I feed this amount in from 24 to 48 hours. The bottom of the feeder is a solid block, $2\frac{1}{2} \times 5 \times 12\frac{1}{4}$, with saw cuts $\frac{1}{4}$ inch, cut into it, to hold the feed. The bees come up through one that is cut clear through, round over a lower partition, and fill up and retire below. These

cuts are divided by thin partitions (that prevent daubing of the bees), and they are all connected by 3 holes crosswise at the bottom, so that as fast as you fill one space, all must fill. The whole is covered with a wire cloth, frame and board cover over all; and is well painted on the outside. Basswood is the best to make them of. As a bee-feeder for general use, they are good. As a supply, they are hardly worth bothering with. If feeding ever becomes a wholesale practice, something on the same principle of four times the size, will be used, I think. There is no patent on them.

All fears of damage to brood by fine tinned wire running through the base of the foundation, are now at an end. The use of such wire holds the full sheets in perfect position, while being drawn to perfect combs. The Given is our choice of all comb foundation. To make full sheets right, in previously wired frames, the press is a gem. A thing \$500 would not tempt me to be without. An excellent article of brood foundation can be made with No. 36 tinned wire incorporated in it, vertically, every 2 inches, with the ends sticking out so that they can be put through holes, in, or on hooks previously attached to the frame, and all in apple pie order. But I think the better way is for each bee-keeper who has too few bees to own a press, to bore and wire his frames with No. 30 (coarser) tinned wire, and fasten the sheets of any unwired foundation to these wires, by the button hook process, which I may hereafter more fully describe. We have found the Given to be the best style of foundation for this hand pressing on to wires; also the best utilized by the bees.

Our bees flew some yesterday, and just a wee bit to-day, and the prospects now are good for this time of the year; for the sun, the glory of earth, is now "returning on his silver wheels." He is coming to us again, with the old certainty; and whose eyes will be gladden more than those of the bee-keeper. We know he will raise the mist, cause the rain, grow and paint the nectar-laden flowers. His genial rays will not only warm our bodies but our minds. In the language of Southey,

I marvel not, O Sun! that unto thee
In adoration, man should bow the knee;
And pour the prayer of mingled awe and love;
For like a God thou art, and on thy way
Of glory, sheddest with benignant ray,
Beauty, and life, and joyance from above.

Dowagiac, Mich., Jan. 29, 1883.

For the American Bee Journal.

Kentucky State Convention.

Owing to the poor health of ex-Secretary Williamson, which prevented him from attending the last annual meeting of the Kentucky State Bee-Keepers' Association, but a very meager report of the meeting was published in the *Farmers' Home Journal* (and I have never seen that), and was not present at the meeting myself, but I understand that G. W. Demaree, of Christiansburg, was elected President and E. Drane, of Eminence, Secretary; W. Cook, Vice President; J. B.

Nall, Treasurer; N. H. Lettell, Mr. Hofstatter and A. Snider, Executive Committee. The meeting stands adjourned to meet in Louisville at a time to be fixed by the executive committee, and not knowing the post office address of the committee, I take this plan to call their attention to the matter, hoping this may meet their eye and that they will take steps immediately to fix the time so that notice may be given in the papers. It is to be hoped that the bee-keepers in Kentucky and those in adjoining States will see to it that we have a rousing meeting. Let all bee-keepers attend, for it is to their interest to do so, and let their light shine; let all novices and beginners attend, that they may learn to make bee-keeping a success.

E. DRANE, Sec.

Eminence, Ky., Jan. 29, 1883.

For the American Bee Journal.

Do Bees Wound the Blossoms?

REV. M. MAHIN, D. D.

In the AMERICAN BEE JOURNAL of Jan. 24, 1883, I find an article by W. H. Stewart containing some things that should not be allowed to pass without some criticism and inquiry.

He holds "that bees wound the bloom of clover, buckwheat, linden, and in fact all other plants, before they are able to extract from them the desired sweet." But he does not offer any proof of his faith in this new doctrine. He does not tell us how the bee wounds the clover blossom. I have watched bees by the half hour, at least, gathering honey from clover, and I never yet saw one insert anything in the flower except its tongue; and any one who has ever seen a bee's tongue knows that it cannot wound anything. The idea that bees wound the flowers to get the honey is contrary to all observations of the structures of the flowers, and of the bees, and of the process of gathering the honey.

Mr. Stewart further says: "Mr. H. M. Morris, of Rantoul, Ill., lives where there is more corn than any other honey-yielding plants, and his bees store large quantities of corn honey each year. He finds that bees work very lively at the base of every leaf, and at every joint from top to root of the stalk. The truth is, that the rind of the stalk is the most tender at that point, and the bees mutilate the rind, making the stalk bleed, and then gather the sweet fluid."

I not unfrequently see something in the bee papers and elsewhere about "corn honey." But corn honey is a myth, except so much of it as is made at the glucose factories. People see bees working on corn tassels, and take it for granted that they are gathering honey; but they are not. There is no honey there to gather. I have sometimes watched bees working on all the varieties of corn grown in this country and I never saw a bee apply its tongue to the flower. The corn tassel has no organs for the secretion of nectar, and it is impossible for it to yield honey. Such at least is my firm

conviction, and will be, till proof of the contrary is presented.

But the bees mutilate the rinds of corn stalks! Well! well!! If that is so we will have to acknowledge that they can break the skin of a grape, and confess that we are liable to the grape growers for the damage to their crops, which we have claimed was done by birds, wasps, and, more than all, by the weather. But the thing is too absurd to be treated seriously. Surely, Mr. Stewart must be joking. If Mr. Morris ever saw bees sucking at the joints of corn stalks (I never did, and I was raised among corn-fields and bees,) the corn was infested with chinch bugs, or some species of plant lice. In very dry weather I have seen bees among the foxtail grass when the chinch bugs were working on it, but only one season.

Huntington, Ind., Jan. 24, 1883.

SELECTIONS FROM OUR LETTER BOX

Size of Hives and Frames.

How many square inches should there be in the brood chamber? What is the right distance between the frames (in the brood chamber), the frames being $\frac{3}{8}$ in. wide? What is the size of sections that will hold 2, 3 and 4 lbs. of honey with separators.

Morven, Ont. W. R. HENWOOD.

[The brood chamber of the hive should be about 2,000 cubic inches, unless a smaller breeding apartment is required for the purpose of driving the bees into the boxes above, when running for comb honey.

The distance between frames, from centre to centre, should be a little less than $1\frac{1}{2}$ inches.

The one-pound section for honey is $4\frac{1}{4} \times 4\frac{1}{4} \times 2$; the two-pound section measures $5\frac{1}{2} \times 6\frac{1}{4} \times 2$. Larger ones are now entirely out of date.—Ed.]

Trial of Packing in Different Ways.

Some of my bees flew a little on Dec. 24th, and I swept the dead bees off of the bottom boards; on some there were more than I desire to see so early in the winter. I hope they will be able to have a cleansing flight before many more weeks. In my two-story hives there are no dead bees. I have 20 hives of bees, packed in different ways, on the summer stands. Those that have the honey above are now in the best condition.

Matteson, Ill. A. WICHERTS.

The Forties Below Zero.

We are having some very cold weather now. The temperature has been very low, continually, since the first week in December, but I shall not venture to tell you just the exact depth that has been reached; suffice it to say that it did go down to the

forties below zero; the snow is about 2 feet deep, and somewhat drifted. As the cold dreary days and long evenings of midwinter pass stormily by, would not a bee-keeper have a thought occasionally about the welfare of his stock? I miss the little bees greatly, during the long term of their imprisonment. O how I should like to live in a land of flowers, where the music made by their tiny wings could be heard from the first to the last day of the years, as they come and go—time would glide so sweetly by.

Mauston, Wis., Jan. 25, 1883.

Rearing of Drones.

I started this spring with 5 good colonies, and increased to 15, by natural swarming. One swarm, coming out on June 17th, gathered 218 lbs. of surplus comb honey; all the others did well. In the BEE JOURNAL for Dec. 20, Mr. Morse speaks of taking frames of honey away and replacing them with frames of foundation. Do you consider that a good practice? What would be the consequences to use all foundation in the brood chamber? Where would they raise drones? Please answer through the JOURNAL.

Toledo, Iowa. H. L. FISHER.

[Mr. Morse mentions the plan of taking frames of honey from the hives, and putting in frames filled with comb foundation in their place. These are readily filled with eggs or honey, as the case may be, and the practice is a good one. The bees will be sure to make drone cells enough on the edges to obtain all they need. This plan is pursued to prevent, as much as possible, the rearing of drones.—Ed.]

Home Market for Honey.

As there was an error in my report, I will give it as it should be: I started last spring with 9 colonies, and have increased them to 29 by natural swarming. I have obtained from them 500 pounds of honey in the comb, and also extracted 500 pounds. I realized from 15 to 20 cents per pound for it in my home market. The bees are all packed for the winter in a bee cellar.

F. A. GIBSON.

Racine, Wis., Jan. 25, 1883.

A Sample of Peculiar Honey.

I left with C. H. Lake a small bottle of honey to be forwarded to you to identify, if possible. The sample sent is $\frac{1}{4}$ clover honey, which does not alter the taste, but I had to add something to darken the shade, before the honey would sell. This honey is, when pure, about as clear as water—the lightest honey in the world, and, to my taste, the best. I took a small sample to the Cincinnati convention, hoping to get some information as to the source from whence derived, and was suspected of putting up “a joke on the convention” with “rock candy syrup.” Dr. Miller said, “glycerine and sugar,” Mr. Bingham proposed “honey dew,”

but I have had this same honey at the same time (June) for 3 consecutive years. This honey candies as white as the best lump sugar when extracted, but will not candy at all in the comb. Dysentery has commenced to show itself, but in hives with the lime protection I have failed to discover a trace of the disease. I should be pleased to have you try some experiments with the lime idea this winter (gratis). I do not claim a cure, but a preventive for dysentery, and if it is not what I claim, I want to know it at once, or as soon as possible, as I hope to solve the problem of “wintering on the summer stands” before I give it up.

F. DELLA TORRE.

Baltimore, Md.

[The honey is candied solid, as white as cream, and very pleasant to the taste, but we cannot state definitely the source from which it was gathered; the white clover flavor seems to be overpowered, so that but little of its taste can be discovered in it. We shall be glad to publish the experiments of Mr. Della Torre with lime; we are not situated so that we can experiment with it now.—Ed.]

Wood Separators,—Thin Boxes.

I have used wood and tin separators during the last 7 years, and now prefer the wood. Would like Mr. Ripley to give us more on the size of honey-box and also any others that wish, until we get a size that suits *merchants, consumers and the bees*. What *thickness* is best for the box? If boxes are 5 or 6 inches high, and 1 or $1\frac{1}{4}$ thick, holding 1 pound, would they be liable to fall down in handling, in retailing, etc. Has any one had experience with such thin boxes? If so, please report on the practicability of them. At present I use boxes 2 inches thick.

P. MOYER.

Hartstown, Pa., Jan. 29, 1883.

Comb Foundation a Great Help.

I had 18 colonies last spring, and I put into winter quarters 34 colonies. They did nothing till the middle of July; since that I obtained from them \$100 worth of comb honey. I could not get along without comb foundation. I think it pays well to use it, as it saves the expense of separators. I have Italianized part of my bees, and like them much better than the blacks.

ALFRED GALE.

Shelby, Ind., Jan. 23, 1883.

Two Queens in a Hive.

The hive was occupied by a colony of pure Italians, with a queen two years old, having her wings clipped. I had been giving my bees a good deal of attention, honey was coming in fast, and the bees were showing signs of swarming. About August 25th, I was passing the hive, when my attention was called to it, by seeing quite a large ball of bees on the alighting board. I pushed them apart and discovered the clipped queen in a dying condition. I took her to the

house, but could not save her. I thought I would try and find out what was the trouble, so I opened the hive and examined it thoroughly. I found the colony in good condition, with plenty of eggs, brood in all stages, and also a young, lively (and I believe fertilized) queen.

Cato, Mich. S. J. YOUNGMAN.

Buckwheat for Honey.

It is customary for farmers, in this section, to "summer fallow" a field intended for wheat the next year. This is done to enrich the land and clean it of foul weeds. How would it do to sow such a field with buckwheat as early as possible after putting on it the usual barn yard manure? Would it give the bees "a lift" in time to plow under about the middle of August, or would the hot weather kill the flowers for honey? Would it help smother out the thistles, etc.? Taking all together, would it be a good way to get honey, and yet help the field for a wheat crop? The experience of bee men is solicited.

JOHN YODER.

Springfield, Ont.

[Buckwheat, if sown about the middle of June, may be made to bloom about the middle of July, instead of in August as it usually does, but the honey is inferior both in flavor and color, and is generally undesirable for market. It would be far better to plant sweet clover for the bees, and it would not interfere with farming operations—as it can be sown in waste places, such as fence corners, road sides, etc.—Ed.]

Double-Walled Hives.

The colonies of bees that survive the last week's blizzard are entitled to a chromo. For four days, last week, the mercury stood between 25° and 30° below zero. I am wintering 16 colonies out of doors, in double-walled hives, with dead air spaces between the walls, made with building paper. If I have any success with them, I may give you a description of the construction of these hives, but if I succeed in freezing the 16, I shall doubtless remain as dumb as an oyster.

JOHN CORSCOT.

Madison, Wis., Jan. 26, 1883.

Good Results.

I started, in the spring of 1882, with 3 colonies of hybrid bees. I increased them to 9, and took 375 lbs. of comb honey.

L. W. GRAY.

Rushville, Ill., Jan. 22, 1883.

Yellow Sweet Clover.

Six weeks before the white variety bloomed, I noticed in my stack yard some of the yellow sweet clover in bloom. Like the white, it does not blossom the first year; but it commences to bloom about May 10th, while the white does not bloom until about June 20th. It gives twice as many blossoms as the white, and the

bees work on it freely when the white is blooming by its side. I suppose the wild pigeons must have brought the seed to my yard.

S. P. SOWERS.

Dunlap, Kansas.

Bees Wintering Finely.

The bees are wintering finely, in the cellar, although it was the coldest weather we have had many years.

L. E. WELCH.

Linden, Mich., Jan. 24, 1883.

Comb Honey Rack.

Please describe, in the BEE JOURNAL, how to make a comb honey rack.

L. A. LOWMASTER.

[It would be very difficult to describe it so as to be understood by the ordinary reader. It will be far more satisfactory to get a sample and examine

it. The engraving shows one used with separators on the Langstroth hive.—Ed.]

Sweet Clover, etc.

What parts of the country are the best for the production of honey? What proportion of advantage has a good timbered district over a prairie pastoral region for bees and honey? Will sweet clover form a permanent sward, or does it die out when two years old, as I have heard? Will it continue in bloom nearly the year round in our most Southern States?

W. M. WOODWARD.

Wilmington, Ill.

[Any place near basswood timber, or where white clover abounds, would be good. In the absence of these you would have to depend on planting for honey, such as sweet clover, alsike clover, mignonette, cleome, figwort, etc. Sweet clover should be planted on the same ground two successive years, in order to obtain a continuous bloom. It blooms from June till frost, and will thrive on any soil and in any climate. A good timbered district has the advantage of being better protected from winds, and from many of the trees the bees obtain honey and pollen.—Ed.]

Water Scarce and Wells Dry.

We are having the driest winter in Maine for many years; the rivers and lakes are very low, many small streams and shallow wells are entirely dry, and people are obliged to melt snow and haul water for daily use in house and barn. The weather is very cold and dry. Bees wintering nicely,

so far as I know. We are reading up and getting ready for next year's work. I am reading "Langstroth on the Honey Bee." This book can never go out of use among bee-keepers. Why can it not be revised, and some additions be made, so as to bring it down to the present condition of apiculture? J. A. MORTON, M. D.

Bethel, Maine, Jan. 26, 1883.

[Mr. Langstroth has commenced a revision, but his health is so poor, that he may never finish it. It is an invaluable work, and will always find a place in every good library.—Ed.]

Wintering Without Bad Symptoms.

I now have 500 colonies of bees; 460 out of doors, packed, and they have no bad symptoms, so far. It was 20° below zero, once, here.

JAMES HEDDON.

Dowagiac, Mich., Jan. 26, 1883.

Honey Plants of Florida.

What are the principal honey plants of Florida, and what part of the State is best adapted to bee-keeping.

Gardiner, Me. O. L. SAWYER.

[The principal honey plants are saw palmetto, cabbage palmetto, sweet gum, snow vine, sweet bay, basswood, mangrove, etc. Many portions of the northwest are good, but the south coast, a little north of the 29th parallel, is said to be unsurpassed for bee-keeping.—Ed.]

Bees Packed are Doing Well.

Bees are wintering well so far, both in the cellar and out of doors, although we have had a very cold winter so far. I have some packed with clover chaff, on the summer stands. They are all right so far. I took a peep at them, one morning, when the thermometer was down to 25° below zero. They were dry and comfortable, with no ice inside of the hives.

D. G. WEBSTER.

Blaine, Ill., Jan. 29, 1883.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new Recipes for Honey Medicines*, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Convention Notices.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

W. M. R. HOWARD, Sec.
Kingston, Texas.

The bee-keepers of Northeastern Michigan are hereby requested to meet at the Dayton Hotel, in Flint, at 10 a. m. on Tuesday, Feb. 13, 1883, for the purpose of organizing a bee-keepers' association. All bee-keepers are earnestly requested to come, and to bring with them any apianian articles of interest that they may possess. A free room, and reduced rates of board have been secured.

W. Z. HUTCHINSON.
Rogersville, Mich., Jan. 22, 1883.

The Tuscarawas Valley Bee-Keepers' Association will hold a meeting in the Town Hall in Coshocton, O., on Feb. 14, 1883, at 10 a. m. Every bee-keeper is wanted at this meeting. Every one interested in bees or honey is requested to be present.

J. A. BUCKLEW, Sec., Clarks, O.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nello's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association will meet at Andover, Ohio, to hold their annual convention, on the second Wednesday and Thursday of February, 1883.

C. T. LEONARD, Sec.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., February 5, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. here.
BEESWAX—It is quite scarce. 1 lb. paying 30c. for good yellow wax, on arrival; dark and off colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival.

BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 10c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@16c. to 14c. Extracted, 8c. to 10c., according to color.

BEESWAX—32@33c. for good.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—The market is at present stagnant. Offerings are not large, but they are receiving no attention from buyers.

White comb, 17@20c.; dark to good, 11@13@14c.; extracted, choice to extra white, 8@9@9½c.; dark and candied, 7@8c.

BEESWAX—We quote 25@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Strained, at 6@7½c., was salable—one lot of 17 bbls. bringing inside figure; but comb, very dull at 16c. to 18c.; and extracted do., 8@9c.

BEESWAX—Steady; choice, 27@27½c.; dark, 26@27c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 19@20c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 9@10c. in bbls. and 11@13c. in cans.

BEESWAX—Source, 28@30c.

A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Choice to fancy white clover honey continues scarce and firm, but buckwheat and extracted honey slow and irregular.

We quote: White clover, first quality, 1 lb. boxes, 24@25c.; fair to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c.

BEESWAX—Only small lots of wax are moving, but the supply is large and prices held firmly for prime.

Western pure, 30@32c.; southern, pure, 31@33c.

D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

If you want the earliest, largest and most prolific of any corn seed in America, write to the famous seed grower, H. C. Beebe, Canton, Ill., for explanatory circulars and engraving.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

C. Olm's Comb Foundation Machine.

Send for Sample and Circular.

1st mt. C. OLM, Fond du Lac, Wis.

Bees for Sale.

50 Colonies of Bees, in Gallup frames, cheap.
200 Colonies of Bees, in Langstroth frames in prime condition.

J. H. ROBERTSON,
36 Atf. Pewamo, Ionia Co., Mich.

A NEW IMPORTATION OF

CHOICE

BOKHARA Clover SEED

has arrived and is for sale cheap.

Apply to CHARLES F. MUTH,
498 mt. CINCINNATI, O.

BE SURE

To send a postal card for our Illustrated Catalogue of Apianian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the lowest prices. Italian Queens and Bees. Parties intending to purchase bees in lots of 10 colonies or more are invited to correspond.

J. C. SAYLES,
518 mt. Hartford, Wis.

HIVES, SECTIONS, &c.

Langstroth, Simplicity, and other hives.

The Lewis One-Piece Section.

The Lewis Two-Piece Sections.

We make the one-piece, two-piece, or four-piece dovetailed or nailed Sections, any size, from half-pound to 6x6 1/2 inches, or any other SUPPLIES for Bee-keepers, made of wood.

4 1/2 x 4 1/2 of any of the above kinds of sections, \$4.50
All other sizes, larger to 6x6, 5.00
Half-pound sections, 3.50

Send for Price List and illustrations of our NEW HIVE for comb honey—something new, just out. Price Lists will only be sent to those that write for them.

G. B. LEWIS,
Watertown, Jeff. Co., Wis., Jan. 1, 1883. 11tf

Friends, if you are in any way interested in

BEES OR HONEY

We will with pleasure send you a sample copy of the Monthly Gleanings in Bee-Culture, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Comb Foundation, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. Nothing Patented. Simply send your address written plainly, to A. L. ROOT, Medina, O.

HEADQUARTERS IN THE SOUTH

For the manufacture of

BEE-KEEPERS' SUPPLIES.

Dunham and Root Foundation a specialty. Italian Queens and Bees from March to November. Send for my Illustrated Catalogue.

5mt. PAUL E. VIALON, Bayou Goula, La.

Fruit Evaporators,

To be used on a common cooking stove, capacity 3 to 4 bushels per day. Price, complete, \$10; in the flat, partly put together, for \$8. A few agents wanted. For particulars and prices for Evaporators, Queen Bees, etc., address

JOHN H. MARTIN,
Hartford, Wash. Co., N. Y.

THE CONQUEROR.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust—break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent postpaid for \$2. Address,

BINGHAM & HETHERINGTON,
Atf. Abonia, Mich.

VOL. XIX.

CHICAGO, ILL., FEBRUARY 14, 1883.

No. 7.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Students of Apiculture.

Dr. Jesse Oren, La Porte City, Iowa, thoroughly endorses the proposition of Dr. H. Besse, on the subject of preparing young men to become practical apiarists, by requiring them to serve an apprenticeship with some experienced bee-keeper, and pass a satisfactory examination before some of the best apiarists of the country, and to such "graduates" a certificate should be awarded by the National Association. This Association to appoint the Board of Examiners, and take charge of the whole business. Here is his letter:

I desire to offer my thanks to Dr. H. Besse, of Delaware, Ohio, for his article on the "North American Apiarian College." It just fills the bill. We want you, Mr. Editor, to give this matter an editorial consideration. The North American Society are sure to approve of the movement. Why not urge the officers of that organization to take all necessary advance steps to have all consummated at our next meeting at Toronto? Will you speak right out in the JOURNAL?

JESSE OREN, M. D.

La Porte City, Iowa, Jan. 12, 1883.

The idea is a good one. What is needed to advance the interests of progressive apiculture is a company of young men, thoroughly practical and progressive, who can be employed to take charge of Apiaries; and such would be in constant demand all over the country. The apiarists of England have adopted this system, and, sooner or later it will be adopted in America.

On page 73 of the BEE JOURNAL for Jan. 31, Mr. James Heddon points out some obstacles in the way of success-

fully carrying out the plan mentioned by Dr. Besse. But Mr. Heddon thoroughly endorsed the necessity of students obtaining information and practical experience, in order to become adepts in the art, and adds:

My limited experience with students proves that this five months of study and practical experiment puts them on the right track, and prepares their minds for receiving all new truths right end foremost. All of my students, who have commenced bee-keeping, are to-day succeeding; two will begin in apiaries of mine, on shares, this spring. My faith is thus great; with these five months instruction, any reasonably apt man can have of me an apiary of 100 colonies on shares, a position which will pay him more than high wages, one year with another, and one in which he can "blunder" and finish his education at my expense. Of course I will direct the operations. I shall get better results than to sell the bees. It will not take five months to convince him that comb-honey production, when properly pursued, pays much better than extracted.

The only obstacle worth mentioning now, to the carrying out of Dr. Besse's proposed method of "graduating," is the unfortunate lack of united action among bee-men, and the "petty jealousies" that are sometimes allowed to mar, in some way or another, the beauty of design, or harmonious working out of the plans proposed by the National Association. We regret that this is so, but shall not here attempt to discuss the "why" and the "wherefore" of such a state of things—we simply admit the fact.

We believe that the officers and members of that body, have, to their utmost, done all that they could to make it a success, and to build an institution which would endure, and be handed down to future ages as an honorable "worker" in the cause of the progressive apiculture of the present century.

Should it fail of attaining this proud position, it will be either because its foes will be too zealous, or

its friends may become disheartened and give up a war, which is quite distasteful to those whose only object is that of rearing a temple to scientific bee-culture, where its best interests may be discussed and guarded, and its devotees meet to confer on the issues of the moment, and the themes of the ever-progressing present.

Could this obstacle be overcome, then a plan might be devised for successfully carrying out "another advanced step," as proposed by Dr. Besse. Time alone will determine this point.

Migrating Apiary.

In last week's BEE JOURNAL, on page 77, Mr. Damkohler, of Clarence, Mo., said that a car load of bees passed through that place on its way south, and said perhaps we could tell him all about that shipment. We had not then heard of the matter, but by the Atlanta, Ga., *Constitution*, of January 9, we obtain the information, and here it is:

A CAR LOAD OF BEES.—On Saturday a car was switched on the East Tennessee & Virginia Railroad, and moved south.

It was filled with bee-hives. One hundred and forty of the latest styles of bee-hives, piled systematically on top of each other, and, to the foreboard, a philosopher with his bed and board.

"Where are you going to take your bees?"

"To Florida for the winter. My name is Thomas McFarland Jackson, and I live in Northern Missouri. I have large apiaries that are forced to lie idle in the winter. I am going to take this car load of hives to Florida, where they can get honey every day in the year. As soon as the clover is out again in Northern Missouri I will take them back there."

"Will it pay you to move them?"

"I think so. It costs me less than a dollar a hive for transportation, and each hive will have from \$6 to \$7 worth of honey in it when I bring them back. That is what Italian bees, I sent to Florida last year, did last winter. Only Italian bees will thrive in Flori-

da, as the moths eat up the common bees."

"Will you live in the open air there?"

"I am going to camp around with my bees. I believe I will bring back about \$1,000 worth of honey in hives that would otherwise lie idle all the winter and be empty in the spring.

This migratory bee-keeping has been practiced from the earliest ages. In Egypt it has kept up for thousands of years, as we stated in the last issue of the BEE JOURNAL. Mr. T. F. Bingham, of Michigan, and others have practiced it; but nearly all have abandoned it, because it did not pay them.

Mr. Perrine, of this city, some years ago, lost several thousand dollars in a similar manner. He had a floating apiary, arranged to run up the Mississippi river from New Orleans, following the bloom till he was to reach Minnesota; but it did not work. Too many bees were lost, and the projector is wiser now, and \$10,000 less rich.

California Honey Crop.

The California *Grocer* of Jan. 27, 1883 is on our desk, with an article "marked," criticising the statement made by Mr. McCaul, that the honey crop of California of last year was only 180,000 pounds and then adds:

The *Grocer* has taken pains to collate the data of last year's honey product from the best available sources. These figures are very nearly, if not absolutely, correct; a statement that will be guaranteed by the fact that they were furnished by Messrs. Geo. W. Meade & Co., of this city, who are well known as the principal handlers of California honey:

San Diego county—Comb.....	300,000
Extracted.....	315,000
Los Angeles county—Comb....	25,000
Extracted.....	170,000
Ventura county—Comb.....	5,000
Extracted.....	180,000
Santa Barbara county—Comb..	6,000
Extracted..	30,000
San Bernardino county—Comb	20,000
Extracted..	10,000
San Benito county—Comb....	10,000
Sacramento county—Comb....	8,000
San Joaquin county—Comb....	11,000
Scattering (both kinds), say....	10,000
Total.....	1,170,000

Making a handsome allowance for any possible over-estimate, we, therefore, find that California's honey product for 1882 will considerably exceed 1,000,000 pounds, which compares rather favorably for us with the 180,000-declaration of our late guest, Mr. McCaul, of New York.

The *Grocer* then proceeds to correct Mr. McCaul's statement concerning

the honey crop of California for the year 1878, in the following language:

In his before-mentioned published report he states the California honey crop of 1878 to have been 720,000 pounds, when in fact the phenomenal crop of that year, by far the greatest ever produced in the State, reached the enormous figures of between 2,250,000 and 2,500,000 pounds. The light crop of last year paid fairly well after all, the average prices obtained being very good; for extracted, 7½ and comb 13 cents per pound. California has been, and we believe will continue to be, the most prominent honey-producing section of the world.

We are glad to have this statistical information concerning the California honey crop. It will be very useful, and Dr. Miller will no doubt be able to use it to good advantage, in his forthcoming "Statistical Table" of the honey production of America.

To take these figures and the table we have already published of the "Honey Crop of Illinois," as officially reported by the assessors, and compare them with the reports that have been received by him, will give a good criterion by which to multiply the whole—and thus give the approximate results of the country at large.

Realizing the difficulties under which Mr. McCaul labored, we can attach no blame to him for his incorrect figures. He could give only such as were reported to him. If his information was only partial (and we do not see how it could be otherwise), his report must be necessarily incomplete, and, therefore, erroneous. The *Grocer* impugns his motive and deals out invectives, but would it not be better to take a charitable view of the matter? All will be thankful for the correction, and cheerfully give our sister State due credit for all that it can show it is entitled to.

Two years ago we endeavored to obtain correct statistics of the honey crop of California (as well as other States) and were unable to give more than a partial statement, for the reason that those interested did not respond to our call. We published what we did obtain, and then one of her champions roundly abused us for belittling its crop, and "applied the lash" to us in a most unmerciful manner!

To show that California needs a reform in this matter, we notice on the same page of the *Grocer*, as the article above referred to, the following editorial, which fully sustains all that we claim. It is headed "A Reform in Grain Statistics;" but the reform

should evidently go far enough to include "honey" and other industries. The editor of the *Grocer* says:

In the matter of collecting and supplying to the public officially-corrected statistics of her agricultural, commercial and manufacturing interests, California is certainly not a progressive State. Such statistics, and especially those referring to agricultural industries, are of great importance to the business community. Our grain interests, already large, are destined ere many years have passed to become a strong feature in the annual product of the country, and it would be well if we inaugurated, in the now comparative infancy of the industry, some system by which reliable data could be furnished to the public as to the results of each harvest during the period of its thrashing. Such a system has been adopted in almost all, if not all, of the great grain-bearing States to the east of us, and has proven of immense value to the manifold interests that are devoted to the culture and sale of, and manufacture from, the cereals. What would be the best system we do not pretend to say, but would suggest the adoption of some such plan as the one now in force in Michigan, which is based upon regular reports, sent to the Secretary of State, from every thrashing machine at work in the State. Let some properly-constituted authority at the beginning of each season supply to every thrashing machine in the State, blank forms, upon which must be noted daily the number of sacks thrashed by each machine; and let those forms be returned to the statistical officer, or bureau, at stated intervals, daily or weekly, as may be thought best. By this means an accurate knowledge can be had of all grain thrashed in the State, to the great benefit of merchants and the public at large; and our annual statistics, which are too often of a highly speculative character, can be correctly built upon a basis of satisfactory information. To the Legislature now in session we recommend this suggestion as one worthy their careful consideration.

Bee-Keeping in North Carolina.

There is some stir now in the highlands of North Carolina about bee-keeping, and the Blue Ridge *Enterprise*, of Jan. 25, 1883, remarks as follows, on the subject:

If there is any special industry which this mountain region is particularly adapted to, it is that of bee-keeping. Tons of honey ought to be gathered and shipped from these mountains every season, while at present there is not one pound sent out, nor one-fourth of the supply gathered which home-demand requires. But in order to make bee-keeping profitable, or even worth pursuing, the old gum and box hive must be abandoned, and the modern frame hive and improved implements now necessary to successful apiculture,

adopted. Preceding these, however, one of the text-books on bee-keeping should be procured, and one of the journals which make bee-keeping a specialty be subscribed for and carefully studied. Two or three dollars invested in this kind of literature would pay an intelligent man or woman, who has a half dozen beegums, managed in the old, shiftless style, a hundred-fold on the outlay, the first season. The AMERICAN BEE JOURNAL, is accorded the first place in the catalogue of bee papers by the leading bee-keepers throughout the country. Being issued weekly it is always in advance with everything new and interesting in bee-keeping. There is no better or more thoroughly practical publication on bees and honey in the world, and all who keep bees and aim to keep them in a practical and intelligent manner, for either profit or pleasure, should subscribe for either the weekly or monthly edition of this paper.

Collapse of Another Glucose Factory.

Mr. A. B. Weed, of Detroit, Mich., has sent us a Detroit paper, and referring to an article it contained announcing the collapse of the "Michigan Grape Sugar Company," says: "All bee-keepers must be pleased to note the decadence of the glucose business. I have been much interested in the exposures which the BEE JOURNAL has made from time to time. I have also been interested in the subject of small sections."

Summed up, the article in question says that the works cost \$300,000 and \$100,000 more have been sunk in running expenses. The high price of corn, the remarkable sugar and molasses crop in Louisiana, last year, the decline in the demand for the product for export, and expensive alterations in their factory are assigned by the manager as the principal causes of the company's collapse.

Remedy for Dysentery.

Mr. J. M. Hicks, Battle Ground, Ind., writes as follows to the *Grange Bulletin*, concerning this disease and remedy for it:

Dysentery is usually brought on by the bees feeding upon sour or impure honey. It is also frequently produced by being disturbed in some way just before a sudden change in the temperature, which, if very cold immediately after they have filled themselves, you may be quite sure your bees will have dysentery. We suggest the following remedy:

Take of good granulated sugar, 4 lbs., and just enough of water to make it into a mush (not syrup) and add 40 drops of carbolic acid, stirring, so as to incorporate all thoroughly, and

then mould into cakes so as to feed your bees, by laying two or three of the cakes of the candy on their brood-frames, and your bees will, in a few days, have relief. This is the best remedy I have ever found after the disease has thoroughly set in. It is a well-known fact that carbolic acid is one of the most powerful disinfectants we have in chemistry.

And now I wish to further say, I have at all times believed that an ounce of prevention was worth at least a pound of cure, and in order to be more successful in the future in preventing this malady, we recommend a free use of rock salt to be placed in a small trough, a few yards from your bees, and fill with water and cobs so that the bees will visit it without danger of drowning. This remedy I have found to be a sure preventive for dysentery as well as the dreadful disease called foul-brood, which has proved to be with some, very difficult to manage.

Free Advertising.

Nothing is more embarrassing to a publisher than to receive articles intended for the reading columns, with matter woven into it, advertising some particular hive, section, foundation, extractor, etc. We have received quite a number of such articles lately, from correspondents, and must here kindly say to all, that such are not acceptable. Our advertisers, who pay for their notices, would consider it unjust to them, if we were to admit such, and would have reasonable ground for complaint. Our advertising columns can be used for all such matter at 20 cents per line, and in that department no injustice will be done to others. This will explain to some why such advertising matter is omitted from their articles, and to others, whose articles would be pointless without the advertising portion, why they do not appear at all.

American Honey vs. German.

The following I have copied from the *American Journal of Pharmacy*, February, 1883, page 98:

"HONEY.—Eugene Dietrich has repeatedly observed that good American honey may be more easily obtained than German honey of good quality, the latter, on keeping, becoming acid by fermentation, at the same time acquiring an unpleasant taste, and when clarified, of a dark color and a caramel-like taste; but fresh German honey yields, on clarification, an excellent product. The cause for the better keeping qualities of American honey has not been ascertained."

—*Randschau*, 1882, page 662.

Thinking that it may be of sufficient interest to appear in your val-

uable JOURNAL, I take pleasure in sending it, though possibly it may neither be new to you or the older patrons of your JOURNAL.

FERD. REPPERT.

Muscatine, Iowa, Feb. 7, 1883.

Separators of Wood.

What is the address of C. Van Eaton, mentioned in connection with wooden separators, on page 43 of the BEE JOURNAL of Jan. 17?

It is Charles J. Van Eaton, York, Livingston Co., N. Y.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., February 12, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. bere.
BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, on arrival; dark and off colors, 17c. 25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7c. 10c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12c. 18c. on arrival.
BEESWAX—Comes in slowly and brings 20c. 30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12c. to 14c. Extracted, 8c. to 10c., according to color.
BEESWAX—32c. 33c. per lb. for good.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—The market is dull, particularly so for comb. Only nominal quotations can be given.
White comb, 17c. 20c.; dark to good, 11c. 13c.; extracted, choice to extra white, 8c. 9c.; dark and candied, 7c. 8c.

BEESWAX—We quote 25c. 28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Strained, at 6c. 7c., was salable—one lot of 17 bbls. bringing inside figure; but comb, very dull at 16c. to 18c.; and extracted do., 8c. 9c.
BEESWAX—Steady; choice, 27c. 27c.; dark 26c. 22c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 16c. 20c. for best white 1-lb. sections; 15c. 19c. for 2-lb. Second grades not inquired after. Extracted very dull at 9c. 10c. in bbls. and 11c. 13c. in cans.

BEESWAX—Scarce, 28c. 30c.

A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Choice to fancy white clover honey continues scarce and firm, but buckwheat and extracted honey slow and irregular.

We quote: White clover, first quality, 1 lb. boxes, 24c. 25c.; fair to good, 22c. 23c.; buckwheat, 15c. 17c. Extracted, clover, 10c. 13c.; buckwheat, 8c. 10c.

BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly.

Western pure, 30c. 32c.; southern, pure, 31c. 33c.

D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22c. 25c.; 2 lb. sections, 20c. 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatam Street.

CORRESPONDENCE

For the American Bee Journal.

The Use I Make of the Bee Papers.

G. M. DOOLITTLE.

"The bee literature of to-day, has more to do with the successful management of the apiary than any other one thing, hence it is of the utmost importance that we have it so arranged that it can be of the most service to us. Although I have learned some things through conventions, and by visiting those keeping bees, yet the major part of the little I know about bees and honey-producing, has been gotten by reading the different bee publications, and putting in practice what I read, thus learning how the thing was done by the experimental knowledge which I gained thereby. Of course, many things I had great confidence in, failed, when I put them in practice, and had to be given up; but the larger part proved of real service to me.

Some people seem to take a bee paper simply for the name of so doing, for when asked if they noticed some very instructive article, their reply is, "No; I do not get time to read much." Such help some by taking a publication, for they help the publisher to give us better paper, type, etc.; but they are just as good as dead, so far as their helping the real life of a publication, or the publication helping them. For such persons this article was never intended, but those who read for the purpose of using what they learn, are the persons I wish to talk to.

When the BEE JOURNAL first comes it is carefully placed in an Emerson binder, and *Gleanings* is treated in the same way. The other bee papers are carefully laid away in a place set apart for them, so that at the end of the year they are in perfect order to be bound, if I wish to have them. If I do not care to be to this expense, I bind them myself by a plan similar to the Emerson binder, or serve them as Mr. Hasty does, driving wire nails through and clinching them, so as to hold them together; or secure them in any way to make them handy for reference, for it is this "referring" to them, I wish more particularly to speak of.

The most important part is to preserve the life of our bee literature, and make good use of it, after we have it all preserved in good order. With all my cares, I cannot find time to re-read the volume a second time to get at the many points in it which are of real value, for much of the matter is hardly worth reading a second or third time. If I was obliged to read all a second time, to get the points I considered valuable to me, I fear I should never get them all. I read it all once, and then I want it so that I can get at that which is really valuable when wanted at another time. To do this, whenever I sit down to read

a fresh JOURNAL, I have a pencil with me, and when I find a new idea, or an old one I wish to farther experiment with, I mark it. In some instances the marks will embrace a whole article, while others call attention to only a few lines. In future years, or at any time I wish to find that which is really valuable in my volume, all I have to do is to read the marked passages and thus get the cream of the whole year in a little time. But I often find that some of the best ideas are suited only to certain seasons of the year, and as my memory is not sufficient for dates and set time, I must have some means to remind me of the valuable points, just when they are of use.

If I read in January the best way to get good queen-cells, or something valuable regarding extracting honey; then in February the best way to take off filled sections, and so on, till my mind is insufficient to contain them all, and have them ready to bring into use at the right time, how can I manage so that I can use what I read, just at the time it would be of the most benefit to me? After studying on the matter for some time I decided on what I call a "Reference Book," which is simply a small blank book, bound in leather. Any memorandum or account book will answer the purpose, providing it has at least 24 leaves in it. This book I arrange similar to an assessor's book, which has the letters of the alphabet from A to Z on the outside margin of the leaves. Out the leaves just as you would to letter them, but instead of lettering them, write on the little square of the first, "Jan. 1st;" on the second, "Jan. 15;" on the third, "Feb. 1st;" and so on, giving one leaf, or two pages, for each half-month, to the end of the year. When I sit down to read, I have this book and a pencil near me, and when I come to any passage, part of an article, or an entire article that I think will be of service to me, either as something new that promises to be valuable, or some new plan of using something already familiar to me, I mark it with my pencil, and then jot it down in my book under the date to which it is applicable. Thus I get all the matter which I consider valuable contained in whatever I read regarding apiculture, arranged in reference to the time it is to be used, in this book.

When January 1st arrives, I look over all there is on this page, and, for instance, commence to make a few half-pound sections as described by J. C. Newman & Son, page 23, A. B. J., by way of experiment, if I chance to find a note regarding them in this little book.

To explain more fully: On page 25, I read how to make a paste for honey labels. As I had always used dextrine, which was inconvenient to procure, I thought this recipe might be better, and the ingredients are also more easily obtained. So the recipe was marked. As the last half of October would be the time I would most likely want to use it, I turn to Oct. 15th (by putting my thumb on that date when opening my reference book), and write, "A. B. J., 1883, page 25.—Paste for honey labels." When this date

(Oct. 15th) arrives, I look over all that is written there, and, as I come to this, I turn to page 25, and there is just what I want, at the right time, for in a day or two I must get my pails of extracted honey ready for market. So I try a part with the new paste, and some with what dextrine I have left. If this paste proves valuable I mark those words on my reference book with a star, or if worthless I draw my pencil across the whole line, thus crossing it off.

If I have made it plain, and I think I have, it will be seen that I have all the real worth of many volumes in this little book, while the matter which was worth only once reading is left out. Different persons would make a different line of selections from what I should, but the plan is a good one, in my opinion, and one that will be of great service to any one who follows it.

Borodino, N. Y.

[The plan is an excellent one. We adopted a similar one for our library over 25 years ago, and it proved very valuable, saving much time and labor.—Ed.]

For the American Bee Journal.

Ohio State Convention.

The convention of the Ohio State Bee-Keepers' Association was held in Columbus, Ohio, Jan. 9, 10, 1883, in the parlors of the Ohio State Journal. The Convention was called to order by the president, Dr. H. Besse; the minutes of the last meeting were read and approved.

The requisites of a perfect bee-hive?

Mr. Riegler, of Adelphi, said, it was formerly thought by our forefathers that a bee-gum was the all requisite; he gave a history of some of the improvements in hives. Among the essential requisites, are proper ventilation and the best manner for production of surplus honey, he noted them as follows: 1. Proper size, 1,800 to 2,000 cubic inches, inside measurement. 2. Movable combs in the brood chamber. 3. Proper arrangements for ventilation. 4. Ease of adjustment for handling bees, and securing surplus honey in best shape for marketing. 5. A proper degree of warmth and dryness.

Mr. Kingsbury, of Mt. Vernon, asked relative to chaff hives. Mr. Riegler said, the chaff hive was not always proof of successful wintering.

The president said, he had wintered successfully in a bee-house; he described his bee-house he built, one with double walls, 6 inches of space filled with sawdust, valves above and pipe tube, made of boards, leading outside, with trap door for ventilation; it cost him \$100, size 10x20 feet. His bees, in the bee-house, did not consume more than 10 pounds of honey to the colony, while those wintered on the summer stands consumed 20 to 30 pounds. He preferred sawdust to chaff, for packing bees, because it was handier to get.

Mr. J. L. Mock, of Columbus, advised to use kiln-dried sawdust for packing. He thought the bees went into winter quarters with too few young bees.

Adjourned till 1:30 p. m.

AFTERNOON SESSION.

The meeting was called to order promptly at 1:30 p. m.

Which is most profitable to bee-keepers, comb or extracted honey?

Mr. Rhulen, of Gahenna, said, people would not buy pure extracted honey, saying they could buy syrup far cheaper (not knowing it was made of glucose, which was poison). A man told him he could feed his bees glucose and sell it for honey and make two to three hundred per cent. on it.

Mr. Benedict said we must educate the people as to the difference between pure honey and glucose; the man who will adulterate his honey can make more money at the beginning, than one who is honest.

Mr. Riegler made some scoring remarks against bee-keepers, who would put glucose in their honey; that it injured the honey interest, and he that would do it should be expelled from society.

Mr. Kingsbury, of Mt. Vernon, answered Mr. Rhulen, that he ought to have gone to the printing office and exposed the man who acknowledged he made honey of glucose; the bee-keepers ought to hang together and drive out adulterators.

The sense of the meeting was to produce extracted honey and drive out the adulterators.

Some one asked how to induce bees to work in sections. Dr. Besse said, put a frame of brood among the sections you want filled.

Shall we encourage the new races of bees?

Mr. Riegler said, he and his partner, Mr. Drum, purchased a Holy Land queen and reared queens from that one. It required about two smokers and three or four thicknesses of veils while handling them, and persons who had difficulty in handling Italians had better let alone the Holy Lands; they will give a bigger dose of stings than you can stand; he gave them credit for some good qualities; they started to work earlier in the morning than the Italians; they gather honey in cold weather, when Italians will stay at home; they do not dart for the face like the Italians, but will go for a person's neck; his new queens were fertilized by Italian drones; he thinks they are about as hardy as Italians; they were more docile when bred down to about the third generation with the Italians.

Mr. Benedict indulged in a humorous description of the savagery of the cross between the little black bee and the Italian; he did not want any acquaintance with that class of insects, but he said a cross between the brown bee and the Italians made a tolerably decent bee to handle.

The most desirable place to keep bees in winter?

Mr. Goodrich, of Worthington, said, for the past two years he had brought

his bees through safely; this year he had used special care, but his bees are restless, and he had nearly decided that no plan is always successful.

Mr. Benedict said, he was cautious about giving advice to beginners; some of them had not followed the advice as it had been given; they were careless, and would then blame their advisers.

The president said, he would throw the doors open at night, and give those restless bees, which were affected with dysentery, more ventilation.

Mr. Hephrey, of Utica, said, his bees have dysentery except two or three colonies, which had less honey than others; those having the least honey were free from it.

Mr. Benedict, of Bennington, said, there is a good deal of dysentery this winter, he thinks the cause to be unripe honey, gathered late.

Dr. Besse said, full combs of honey would compel the bees to gather between the combs when they ought to have empty cells to get into; said he had given an ounce of laudanum and the same of essence of peppermint to the gallon of syrup; he found it a cure for dysentery.

Mr. Riegler had observed closely what the members had said in regard to their losses by dysentery; he believed, from their description, the bees were too warm and had not ventilation enough; he gave the plan of his partner, Mr. Drum, for wintering out in a shed, with doors to open in warm weather; if he had bees with dysentery, he would take their combs away and give them clean combs, or wash and dry them, and put them back in the hives.

Mr. Benedict gave his plan of giving bees a flight in cold weather; for this purpose he would use hives with loose bottoms and built so that they can be attached, and stacked one above the other. Take them into a warm room and cover the brood frames with clean paper, leaving open a place for the bees to crawl into the upper hives; they will then fly and eject the feces; when they return to their places in the lower hive the upper ones can be cleaned and removed; the paper should be replaced by a clean quilt, and their condition is improved. He believed we would have trouble with the bees, so many are reported with dysentery. "I think they gathered something last fall which was injurious; the honey should all be extracted, all of it, and give the bees clean combs and feed them white sugar syrup; it might be smart weed honey, perhaps not, but we should extract it and have the honey examined to ascertain whether it was pure, or bad for bees."

Mr. Riegler would be afraid to feed the bees sugar syrup in winter, unless they could seal it up.

Mr. Benedict did not think it would sour or ferment.

The chairman appointed Mr. C. M. Kingsbury as soliciting committee, and 12 new members were added to the Association.

Mrs. Jennie Culp, of Hilliards, O., said she was afraid she had killed

some of her bees, by handling them when the weather was too cold. She asked if it is best to leave the quilt on the frames that was on all summer or use a new one? Mr. Goodrich said it was best to put on a fresh quilt. She asked if she should use the same combs, if they are mouldy? Mr. Benedict and the secretary coincided to use the mouldy combs; the bees will clean them up and use them.

Mr. M. J. King, of Chardon, O., asked which is the best bee? Dr. Besse said, "The golden-banded fellows." Mr. Benedict said, "The pure Americanized Italians, those which have been specially bred for honey producers."

Mr. Riegler asked, "Should farmers keep bees?" The secretary said those who neglected their bees were not the successful bee-keepers, and careful bee-keepers were not always successful.

President Besse and Mrs. Jennie Culp exhibited samples of extracted honey.

The president appointed as a committee on exhibits: Messrs. Benedict, Rhulen and Riegler; and as a committee on the revision of the constitution: Messrs. Riegler, Benedict and Kingsbury. Adjourned to 7 p. m.

EVENING SESSION.

Reports of committees were called for. The committee on revision of constitution reported in favor of erasing certain words in Article VIII of the constitution. Adopted.

The committee appointed on exhibits reported as follows: Eight samples of extracted honey by President Dr. H. Besse; 2 of his own production; 1 each of Palmetto honey, from Florida; buckwheat, from Kentucky; horsemint, from North Texas; horsemint, from South Texas, early; horsemint, from South Texas, late; goldenrod, from Ohio, and white clover from Ohio; all of which were very interesting to the committee and members who sampled them. The flavor of the different varieties is very distinct; some fine; others not so good. Mrs. Jennie Culp, of Hilliards, showed 1 bottle of white clover honey and 1 of linden, both very fine. A smoker, from W. C. R. Kemp, of Orleans, Ind., which contained some good points.

The best sized sections.

Mr. Riegler said there are several sizes or forms of sections, the one-pound or Root section should be used by those who use the Langstroth frame; it is convenient for families of small means. Voted that the one-pound section is the best for surplus honey.

Mr. Benedict said, in regard to the spacing of brood frames, I am very careful to keep them in proper space, and, as near as possible, the same distance apart, as the bees construct them naturally.

Mr. Riegler was in favor of spacing frames 1½ inches apart, from center to center, which is the proper distance for the bees; he likes the Huffman arrangement for spacing, especially for beginners.

Will it pay to cultivate honey producing plants and trees for bees?

Mr. Riegle thought the linden profitable for honey and shade, also the black locust is a honey producer, and the locust is profitable for timber; he had planted 5,000 young locusts; he believed the borer would not infest the locust, when it was planted close for timber; he believes if any plant will pay for honey alone, it is sweet clover (melilot); he does not think alsike will pay for honey alone.

Mr. Rhulen had 25 acres of alsike clover; the hay is far superior to the red clover.

Mr. Benedict believes the yellow willow produces more honey than the apple blossoms.

The secretary said he had planted 50 linden trees, and they bloomed the second year after planting.

The committee appointed by the chairman to confer with the State Board of Agriculture, were Messrs. Riegle, Benedict and Hephrey. After taking a recess, the committee reported they had seen the Secretary of the State Board, and could do nothing until after the election of the new Board.

Adjourned till 9 a. m. to-morrow.

SECOND DAY.

Jan. 10. Meeting called to order at 9 o'clock a. m. The subject for consideration, was "Facilities for Exhibits at the State Fair." The president thought we ought to have a suitable building for exhibits. Mr. Benedict and Mr. Riegle thought there should be about one-fourth of an acre of ground enclosed with wire fence, attached to the hall, for the use of bee-keepers. Messrs. Benedict and Hephrey, on committee to confer with State Board, were excused, as they had to go home, and the chairman appointed the secretary in their stead, who, with Mr. Riegle, were to petition the State Board of Agriculture, on Thursday, for better facilities for exhibits on the State Fair grounds.

The president presented the following plan for a report of each member:

Gentlemen of the Convention: It is my duty, as the Ohio Vice-President of the North American Bee-Keepers' Association, to make as full and complete a report as possible of the number of colonies owned, and amount of honey, wax, etc., produced during the incoming year in the State of Ohio; all bee-keepers will confer, not only a favor upon your president, but upon the whole fraternity which extends throughout the greater part of North America, by filling out the following statistical report, and sending the same to Daniel Spear, Sec., Cardington, Morrow Co., O., just before our annual meeting, which will be held during the State Fair in Columbus. In this way you can greatly assist me in this work. Now, gentlemen, I should justly feel proud if you would assist me to so represent the great commonwealth of Ohio in the North American Association, as to have the fullest and best report of any State, Territory or Province; and this we can do if you will have the kindness to assist me in so doing.

1. Name, P. O. address and county.
2. No. of colonies owned Sept. 1, 1882.
3. No. of colonies owned May 1, 1883.
4. No. of colonies owned Sept. 1, 1883, or at time of next annual meeting.
5. No. of colonies showing yellow or golden bands.
6. No. of colonies of blacks.
7. No. of colonies sold during the year.
8. No. of colonies bought during the year.
9. No. of queens sold during the year.
10. No. of queens bought during the year.
11. No. of lbs. comb honey taken during the year.
12. No. of lbs. extracted honey taken during the year.
13. No. of lbs. wax honey taken during the year.
14. Kind of hive used or preferred.
15. How and where wintered.
16. If fed during spring, and if so, how liberally.

This plan was adopted by the convention.

Mr. A. S. Goodrich asked whose manufacture of comb foundation is best? Dr. Besse said, "The Dunham." Mr. Goodrich asked if it made any difference which side of the foundation is fastened to the top bar? The secretary had never found that it made any difference.

Mr. Riegle said, "the Dunham foundation pleased him best. Some three years ago foundation was manufactured in the East, having wire in it, which troubled the bees; they tried to gnaw out the wire. Lately the foundation invented by Mrs. Dunham (credit to the ladies), was preferred, because the walls are stronger." "The flat-bottomed foundation was another improvement." "The fish bone can be detected whenever it is used in surplus comb honey," he showed, by diagram, his plan of putting full sheets of comb foundation in brood frames.

Mr. McDowell asked, is it any advantage to introduce fertile queens after a first swarm?

Mr. Benedict said, his plan for multiplying colonies, was this: Have ready a good supply of old comb in movable frames, drum out the bees and queen, put them in a new hive, place it on the old stand; place the old hive on a new stand, and the next day give the old colony a fertile queen. This plan keeps a laying queen in each hive. If further increase is desired, go through the same process in about 15 days, with the old hive, as before; there will be just as much larva and brood, as when first divided. By following this plan the old colony is continually producing more bees; in this way we improve our natural swarming.

Mr. Riegle said, a natural swarm will always accept a queen when it swarms.

Mr. Benedict said, bees gathered more fall honey last season than they had gathered at that season of the year for 30 years.

Mr. Hephrey stimulated his bees in April; they swarmed in that month,

which alarmed him; he looked and found they had no honey.

The following is the statistical report of members:

Mr. S. C. McDowell, 250 lbs. of surplus extracted from 4 colonies; buckwheat and smartweed honey.

Mr. Rickenbacker, about 25 lbs. to the colony, fall honey.

S. H. Rhulen, 21 colonies, wintered on summer stands. I found 10 of them were starving; fed 200 lbs. sugar syrup; increased to 33 colonies; got about 2,500 lbs. of comb honey and 1,000 lbs. of extracted honey.

Earle Clickenger had 9 colonies; had no increase; got 450 lbs. of comb honey from 6 colonies; but no honey from 3 colonies.

C. D. Bennett had 14 colonies in spring; got 550 lbs. of comb honey and 250 lbs. of extracted; the season was poor in the spring, but good in the fall.

A. S. Goodrich had 30 colonies in spring, in good condition; the fore part of the season was very bad; had to feed up to June 5, to keep them from starving; got nothing from fruit blossoms, and very little honey from white clover; increased from 30 to 54; they gathered very rapidly from fall flowers; the hives are very full.

Mrs. Jennie Culp, I am an A B C scholar. I gave each colony 1½ lbs. of maple sugar; had 22 colonies; increased to 30; I extracted June 1, put the honey in 6 gallon stone jars to ripen; had over 4 barrels of extracted honey at Fair time (Sept.); extracted after the Fair; altogether had nearly 5 barrels of honey; attribute my success to feeding in spring, and to having plenty of surplus combs; I sold all my surplus honey for 20 cts. per lb.

A. C. Castle, I am a novice; have 15 colonies of black bees; sold none, increased to 22; got 275 lbs. of comb honey; the fall yield was the best.

J. G. Shiably, had 3 colonies in spring (2 in box hives and 1 in movable frame); got nearly 150 lbs. of comb honey; I am a beginner; the fall yield was the best.

M. S. King, commenced with 13 colonies; worked for increase rather than for honey; the season was very poor. Mr. Johnson, in my vicinity, got only 3 lbs. to the colony.

Mr. Riegle: I had in the spring 50 colonies; yield from maple and yellow willow, followed by fruit blossoms and poplar honey, then white clover; I got the least yield last season from white clover for several years; got 700 lbs., mostly extracted honey; hardly any increase; the fall yield was from smartweed and asters.

Mr. Drum increased from 50 to 75 colonies, and had very little honey.

Mr. Benedict gave his plan of working for extracted honey. Have your hives made to fit, one on top of another; put a colony on the top of the first; after three days let them go together. Do not extract till fall, but tie up one hive above another, and give them combs or foundation to work on and fill.

President Besse commenced the spring with 55 colonies; increased to 107; put into winter quarters 101 colonies; got 1,000 lbs. of comb honey and

1,000 lbs. of extracted, about one-half clover honey, and the rest was fall honey; sold the extracted for 20 cts. and the comb honey for 22 cts. per lb.

Voted that Mrs. Jennie Culp had produced the most honey, for the number of colonies she had, of any member of the Society.

A vote of thanks was tendered the Ohio State Journal Co., for the use of their parlors, in which the Bee-Keepers' Convention was held.

Voted to adjourn to meet at the call of the secretary, at some place in Columbus. DANIEL SPEAR, Sec.

Report of the committee appointed by the O. S. B. K. Association, to petition the Ohio State Board of Agriculture for a building, in which to exhibit bees and apianian productions:

COLUMBUS, O., Jan. 11, 1883.

To the Honorable Directors of the Ohio State Board of Agriculture:

GENTLEMEN—We, the committee appointed by the Ohio State Bee-Keepers' Association, in convention assembled in Columbus, O., on Jan. 9 and 10, 1883, to represent to your honorable body the interest in apiculture and the demand for our productions, and urgently request that you erect, upon the Ohio State Fair grounds, a suitable building, with about one-fourth acre enclosed ground attached, in which to exhibit bees and apianian productions.

Plan and approximate specifications herewith attached for Apiarian Hall.

We believe the size of this hall, 25x50 feet, to be sufficient for our present use, with space left at one end for extension of hall, if our interest in the future should require it.

SAMUEL D. RIEGLE,

DANIEL SPEAR,

Committee.

For the American Bee Journal.

Whitford's Surplus Case, etc.

JAMES HEDDON.

I was much interested in Mr. Leroy Whitford's description of his surplus case. The more so because I have been over the ground. I have made and tested the T shaped tin supporters mentioned.

All are aware that I use a $4\frac{1}{4}$ in. high division piece of wood, nailed to the super. Well, on trying the tin rests, I returned to the old wood divisions, for the following reasons:

The tin rest does not, like the wood divisions, strengthen the case. They somewhat hold the sections apart at the bottom, with no corresponding wedge to stop up the corresponding opening at their tops. This means bee-glue. They are very likely to get knocked and bent out of shape by the least touch. It requires much more care to insert the sections in their proper place, than with the wood divisions. They are but little cheaper. You must use a case not the proper length to fit the regular Langstroth hive, or use sections not of such sizes as are commonly used by those using broad frames. I see no good in the

movable divisions, except in case of where a bee-keeper wishes to alter his cases to suit a total change in size of sections. Then the same change can be made (with a little more trouble) with the case, using the permanent divisions.

I see no use in using three cases, each holding one-third of half-pound sections, and two-thirds of one-pound, when you can just as well devote two cases to the one-pound and the third to the half-pounds throughout; but I do see many reasons for having the shipping crates hold all sorts, and ours does; each crate holds, as follows:

12 $4\frac{1}{4}$ x $4\frac{1}{4}$ x2 (or 6 to the foot).

14 $4\frac{1}{4}$ x $4\frac{1}{4}$ x1 $\frac{3}{4}$ (or 7 to the foot).

21 $4\frac{1}{4}$ x2 13-16x1 $\frac{3}{4}$ (or 7 to the foot).

24 $4\frac{1}{4}$ x2 13-16x1 $\frac{1}{2}$ (or 8 to the foot).

In each instance, the thickest of the one-pound and half-pound sections are used with separators, while the thinner ones are not. I consider an assorted crate an advantage on the market, but an assorted case is a disadvantage on the hives.

I used my T rests at the extreme bottom of the case, but I think I understand that Mr. Whitford (page 56) must place his so that the bottoms of the sections rest above the bottom of the case. Now, if the case rests on the top of the hive (as all cases should) and the hive has a bee space above the top bars of the frames (as all hives should), how about your proper bee space between the bottoms of the sections, and the top of the frames, where no honey board is used?

There is hardly any system of surplusage, that is so "awfully awful," that it does not possess some advantageous features over all others, and I think if I could be persuaded to use separators at all, I should use them in connection with broad frames, but not such broad frames as I used before, or any now in general use exactly, but such as I am now making for the coming season, and "the box of tin" experiments.

Those who advocate wood separators, 1-16 and $\frac{1}{8}$ thick, do not tell us how long it takes the bees to glue up the less than bee spaces that the separators cause between the end pieces of the frames, at the top and bottom, where the narrower separators fail to fill it up. How long will so many beekeepers violate the scientific principles laid down by Langstroth?

I think that there is now extant all the conservatism needed, regarding the half-pound sections. The idea that their littleness, or tare, will condemn them, I think will be found to be an error. I shall use 20,000 next season, and fully expect to increase the number the following season. In one apiary (of over 100 colonies, spring count) I shall use nothing else. As I said in a recent communication, I believe, when once on the markets generally, more thousands of these half-pound sections, will be used than of any other size. The present markets may not, as Messrs. Crocker & Blake say, demand very many half-pound sections, but these little cards of honey will, I think, not only fill a certain demand already existing, but increase that many fold. Let us see.

This year's numbers of the "Old Reliable," BEE JOURNAL are full of progressive articles. I sometimes get "too full for utterance," when reading them. I begin to think that after I am so old that my hair is white, (that is, the little row, just around above the ears), teeth all out, nose and chin nearly caressing, eyes retired a half inch, etc., that I shall try to tell the boys "how we used to do," and where they will go to, if they don't stop using so many new-fangled fix-ins." But I expect to stop when death gets me in his swath. I can not afford to "forever write," like Mr. Robinson.

But I would like to tell Dr. Tinker and G. M. Doolittle, why I believe their ventilation theories will be found to have little to do with successful wintering, when we get this branch of bee-keeping under our thumb, which I earnestly believe we shall soon do; and to tell William Roberts to put a little salicylic acid into the paste, the formula of which was given on page 25; also to tell S. F. Newman (page 26) why one of his apiaries has dysentery, while the other three have not, all being "prepared for winter in the same manner." Also to give R. Dart what I think to be much more efficient and easier manipulations for prevention of after-swarms than his, as given on page 39. I hope to get at an article on this subject before the season for practice begins.

I wish Mr. Isham (page 53) would send me a sample of his wood separator, and tell us through the BEE JOURNAL how he puts up with, or avoids the glue difficulty, spoken of above.

I want to say to D. Videto that since I wrote the "Cell by Cell" article, I have used the "brass clock wheel," and wooden wheels, but found still better, Mr. Root's button hook process, of fastening wires to foundation.

I think we owe S. Corneil (page 69) a large debt of gratitude for his valuable article on "The Carbonic Acid Gas Question;" it contains just the information (seemingly beyond all successful controversion) that I most wish to know. For the sake of our own health, not that of the bees, for I feel that neither carbonic acid gas nor dampness, are, either or both, causes of dysentery, which I will try to show in an article on that subject which I will write as soon as this winter's experiments are over.

I am not a little surprised at Dr. Tinker's advice to set the sections down on the brood frames. We have been through that mill, graduated, and received our papers, and I therefore take the liberty to warn all beginners against violating the instincts of the bees, by doing any such thing. If they do, the bees will, with their glue and stings, punish them for it.

Before closing, I must say to Dr. Baker, whose lively literature is a pleasure to read, that, according to my experience, crosses between the brown Germans and dark Italians, are excelled by no bees known for their good behavior, and should not be called "irascible insects," while the term "business neighbors" is very applicable to them. I too enjoy the beauti-

ful, but, to gratify this propensity, I would no more think of cultivating "beauty spots" on bees, than would the wood-chopper of paying two prices for a beautiful ax! I wish to use merely the best bees I can get, that will, with the least friction, most certainly procure for me the "filthy lucre," with which (after obtaining the necessities of life) to beautify my home, my nine and sixty other possessions, before the abdomen of my bees. I am sorry the Doctor should advise such a dose, as a mixture of honey, eggs, blackberries and milk, as a panacea for poverty. "It won't do, Dr.: it won't do;" such prescriptions will not cure. I thank him for putting our side of the question ahead. I doubt not experience will keep it there.

Dowagiac, Mich., Feb. 2, 1883.

The Compositæ, as Honey Plants.

L. H. PAMMEL.

Among the many flowering plants none are better adapted for honey and none are more profitable for bee-keepers than the various species belonging to the compositæ family; not only because they are productive in honey, but also because they are continual bloomers. A well-known example is the common dandelion, that starts to bloom early in April or May, continuing to bloom in favored localities until frost.

Taraxacum den leonie is very rich in honey, and, according to the observations of Sir J. Lubbock, the honey is so abundant that it rises quite a distance in the floret.

The dandelion, consisting as it does of a great many small florets, must necessarily bloom at different times; making it exceedingly productive, both in honey and pollen, for a long time.

The different species of *Taraxacum* are widely distributed throughout the world, and there is, perhaps, no portion of the United States in which the dandelion does not bloom with profusion. It is one of our earliest honey plants, and is certainly visited more frequently by bees than many other honey plants.

Honey bees are not the only ones that secrete their nectar, but on the authority of Herman Mueller, no less than 90 species visit it for this purpose.

Our various lettuces are valuable honey plants, the flower heads are smaller than those of the dandelion, and not so conspicuous, yet they contain an abundant supply of honey and are in bloom constantly from July to frost, especially our wild species, some of which are very common. I have found, at least, that wild lettuce was very common about Madison; less common is the prickly lettuce, but, as a honey plant, it is as good in all respects as the cultivated lettuce.

Closely allied to *Taraxacum* and *Lactuca* are *Hieracium*, hawk-weed, *Sonchus*, snow thistle, and *Nabulus*, rattlesnake root.

They are all late flowering plants, especially *Sonchus* and *Nabulus*. Al-

though they contain an abundant supply of honey it is not sought so eagerly, on account of the abundant solidagos and asters, in which the nectar can be obtained easier; that is, the expenditure of labor is less.

My Comb Honey Rack.

JOHN HODGSON, JR.

DEAR EDITOR—According to promise, at the Northwestern Convention, I send you a honey rack, with the following description of it:

The engraving represents a comb honey rack for sections with portable side and bottom board, to be used on the top of the hive. This case, A, being made to hold 28 sections $4\frac{1}{4} \times 4\frac{1}{4} \times 2$ inches, without separators, is just $4\frac{1}{4}$ inches deep, without bottom board. B is the portable side held in its place by the V-shaped beveled wedges, C.

The honey board is composed of 7 slats, running from end to end, fastened together with a $\frac{7}{8} \times \frac{3}{8}$ strip across each end. The slats are one-half inch apart. The center board E, $4\frac{1}{4} \times \frac{7}{8}$ inches, is to hold the sections squarely in place in the center. The section

board is intended to take the place of a row of sections; when it becomes necessary to have the bees work only in a part of a set, one or more can be used.

To fill the rack with sections take the keys, C, out, and remove B, and place the sections in the rack on the honey board; then replace B, starting in the keys, C; put in the center board, E; press down the keys, C, tightening the sections as desired.

To get the sections out, when they are full, remove the keys, C, and take the rack from around the sections. If desired to examine the brood chamber, remove the rack, sections and honey board, all together, from the hive. Observation holes, in the sides, have glass placed in grooves in the inside of the rack.

Most of bee-keepers that have used it, advised me to have it patented, but I have concluded to give the invention to the bee-keepers.

Pewaukee, Wis., Jan. 16, 1883.

For the American Bee Journal.

How My Neighbor Winters Bees.

H. J. NORTHRUP.

Having seen so much in the BEE JOURNAL about wintering bees, I thought I would describe how Mr. O. winters his bees. About December 1st, or earlier, if the weather becomes settled cold, Mr. O. places boards on

the ground along by a tight board fence. Placing the hives close together on these boards, leaving a space of a few inches between the row of hives and the fence, he raises the hives about $\frac{1}{2}$ inch, by putting blocks under the corners of the hives; lays a narrow board, 6 or 8 inches wide, slanting against the front of the row of hives so as to make an air space; he then takes heavy paper, old carpets or blankets (paper is best), lays them on top of the row of hives, allowing them to hang down the front, near to the ground; lays boards, sticks, etc., on top, to keep the paper in place; fills in between the hives and fence with forest leaves or straw; places a layer of straw in front of the hives, with a wide board, laid on its edge, against the straw, to keep the straw from falling away; roofing the whole with old boards, or anything that will turn the water from the hives. In very cold weather he stops the holes at the ends of the boards, making the air space, and opens them when the weather moderates. Mr. O. tells me that he has practiced this method 12 years and has never lost a colony, that was in fair condition when put into winter quarters. I have practised the same two winters with equal success.

Lansingburgh, N. Y.

For the American Bee Journal.

Wintering, Marketing, etc.

WM. CAMM.

I put 57 colonies into winter quarters, with plenty of stores. The hives run for comb honey, had sections removed and quilt spread in the bottom of the honey rack, which was covered with dry wheat chaff, and the rack left on the hive. All hives were chaff-packed, then set side by side, on timbers, so as to raise the sills 5 or 6 inches from the ground, a pole laid on the top of the hives, and then corn fodder reared thickly on the north side of the hives, and thinly on the south side, except a few single-walled hives that were covered deeply on both sides.

I intended to say that I was selling comb honey at 25 cents, and extracted at 20 cents; but the "typo" got this statement reversed, or I made a mistake in writing it. It sells but slowly at these prices, though I have the sections nicely cleaned, allow net weight, and put the extracted, almost wholly clover honey, in neat and handy packages.

Cannot the Board of Railroad Commissioners do something about reducing the freight on honey from double the rates of syrup?

It is hard for a man to carry pure clover honey to the store and be refused 20 cents, when dark adulterated stuff stands before him on the shelves at 25 cents. The most discouraging thing in bee-culture is the low price of extracted honey, given in the papers. Discrimination is even made against candied honey, though candying is a certificate of purity, and nine out of ten like candied better than liquid.

Sometime ago a paper remarked, excusingly, that many worthy dealers,

rather than face financial ruin, sold adulterated articles. It seems to me that we have as much right to avoid financial ruin as anybody; and putting the matter in the light of self-defense, it is hard to say who, or what class, should not be excused. We must look to legislation for a cure; but not to repressive legislation. Those who actually till the soil, pay so much, or more, every year, directly or indirectly, to get at the land, than would liquidate the national debt; this drives tens of thousands from the land into towns, cities, necessities and crimes; hence the trades and professions are over-crowded, while the avocation—agriculture—upon which all depend, primarily and ultimately, has far too few engaged in it; and those who follow it, instead of trying to make one acre produce double, are trying to get two acres where they now have but one. I only hint at the matters we must deal with, to suppress, or rather prevent, adulteration. There is no country in the world, perhaps, where laws are more stringent or better executed, especially with regard to adulteration, than in England, and yet we are told that London is the paradise of adulterators.

Murrayville, Ill.

[We think our correspondent is in error about London being "the paradise of adulterators." English laws against adulteration are very stringent, and well executed. We wish we could say this of America.—Ed.]

Translated from *Illustrated Bienenzeitung*,
by A. R. Kohnke.

The Giant Balsam as a Honey Plant.

PROF. DR. MUENTER.

Through the kindness of Mr. Reuter, of Sanssouci (H. M. court gardener), the apicultural exposition of the Baltic Central Bee-Keepers' Association at Potsdam, in September, 1881, was furnished a specimen of the giant balsam. It is no new plant, but the attention of the bee-keepers was called to it then for the first time as a honey plant. Some few bee-keepers there, knowing the plant and its value, praised it so highly that Von Behr Schmoldow, H. M. chamberlain, was induced to try to cultivate it, with reference to honey-producing and hardiness. Having obtained a small quantity of the ripe seed, he charged his gardener with the raising of the plants therefrom. The seeds were planted in September, 1881, in drills, $1\frac{1}{4}$ inches deep and about $3\frac{1}{2}$ inches apart. With only a light covering, they endured the winter well, and were transplanted in the spring of 1882, about 32 inches apart. At the beginning of September, the plants had attained the height of 6 to 8 feet, and were covered with many thousands of blossoms; and, without exaggeration, there was a bee on each, so that new comers would hardly be able to secure one, not in possession of some other.

Last September, small quantities of the seed were distributed among the

members of the Horticultural Society of Pomerania, to raise as much seed as possible, of which the District Bee-Keepers' Societies will get their share, next year. Many plants have a reputation as good honey producers, but the giant balsam excels everything by far; the more so as it blooms at a time when there are but few other honey-yielding plants, and these furnish it in very small quantities. It will pay to raise it wherever possible. It blooms in August and September.

For the American Bee Journal.

Small Packages of Comb Honey.

ARTHUR TODD.

In my capacity as delegate to the International Exhibition of 1878, at Paris, for the apicultural interests of Algeria, I called upon Madame Jarrie, a leading box frame bee-keeper, living near Paris, and who has given her name to a certain style of hive used in France. Having explained the working of her hive to me, this lady proceeded to show me some of the results therefrom, and one exhibit struck me forcibly at the time, which the revived talk upon "small packages" recalls to my memory.

This exhibit was neither more nor less than a section about the size of a Harbison Californian section, divided by cross pieces of wood into six portions, each portion filled with comb honey. "This," said Madame, "is the comb honey package of the future; a single spoonful can be removed without causing all the rest to bleed, and smear everything it comes near."

"But will it sell, put up like this?" I asked. "This is an article *de luxe*," she replied; "and people will pay for that. I have sold all I had at 5 francs per pound (\$1.00), and could have sold more, etc."

I went back to Algeria, and fitted up some Harbison sections in the same way—fitted in small pieces of white comb, and had them filled, and personally proved that it could be done without in the least altering the shape or size of the present "one" and "two-pound sections." I have thought out a simple plan for subdividing the same, and inserting the very thin comb foundation all in one operation. I hope, Mr. Editor, you will publish it and so prevent any patent claim being brought out later on upon the same thing.

To subdivide a section into four parts only requires four (4) pieces of very thin wood cut thus:

Two of these, interlocked, cut the proper size, and the ends touched with glue, are placed inside a section. Now, upon the cross, formed within the section by these two interlocked pieces, lay a piece of thin foundation, cut to the size of the section. Upon that again place two more of the pieces of wood, interlocked; the crossing of the wood of the uppermost will now press the wax down upon the

crossing of the first pair, and the adhesion of the wax and the wood will be sufficient to keep all in place. I enclose four sample pieces, to illustrate my method, and it will be easily seen how the increasing the number of interlocking slits in the pieces of wood will increase the number of squares of honey in any section.

Philadelphia, Pa.

For the American Bee Journal.

Returning Swarms, Uniting, etc.

L. DENSMORE.

It was the poorest season for bees and honey that I ever knew, in over thirty years. The season opened wet and cold, and although there was plenty of white clover, it secreted no honey, and up to June 25th I had to feed some of my strongest colonies. In July, basswood opened, and such a rush for honey I never saw before. Colonies were strong in numbers; most of my Italians had nine full frames of brood and they were obliged to store their honey in boxes. I started with 27 colonies, increased to 41, and put back 8 swarms. The swarming lasted only while basswood was in bloom.

Some one was enquiring for a successful way of putting back swarms. Give them an empty hive and let them stand until just before night; look through the parent hive, cut out all of the queen-cells and shake the bees in front of the hive. Catch and clip the queen's wing, while returning; put on an empty crate of boxes, and all is right. I never had a swarm come out the second time. Care should be taken to keep plenty of room for surplus honey.

I had two colonies of black bees that would not try to defend their stores against robbers. They would let the Italians carry off their honey, so I pinched the heads of the queens and united them with an Italian nucleus, having an Italian queen, and there was no more robbing.

I have united by the onion process, and it is a success, every time. Give them the onions at least 36 hours before uniting. I have united colonies and nuclei, and, for experiments, exchanged queens from one hive to another, and from nuclei to black colonies with perfect success, usually leaving the onions in the hive, sliced up, 48 hours; and to make everything absolutely certain I gathered the dried bloom and seeds of catnip and used it for fuel in the smoker, giving them a good smoking after uniting. It leaves a strong odor of catnip. By this process I have never lost a queen, or had any fighting after uniting.

A portion of my Italians and my Holy Lands, crossed with Italian drones, work readily on red clover. My black bees (4 colonies) gathered no surplus and but one of them swarmed. One apiary of 70 black colonies, spring count, gathered but little surplus honey, and, as far as I can learn, but few bee-keepers in this section had any surplus honey. I got 1,500 pounds of nice box honey, and sold it for 20c.

per pound. I do not think I should have got one quarter of that amount with all black bees. Will the tulip tree furnish honey, here in the north, equal to the basswood, and is it as rich a grower and as hardy?

Livonia, N. Y.

[The tulip blooms in May and June and is a very ornamental tree, which sometimes grows to the height of 130 feet. In the South it yields honey profusely, but in the North it yields much less; the honey is not equal to basswood. It grows rapidly in deep, rich soil, after being transplanted when two years old. It is often called "whitewood."—Ed.]

SELECTIONS FROM OUR LETTER BOX

Balled Queen—Grape Sugar.

What is meant by a queen being balled, as spoken of in the BEE JOURNAL, page 21? What is grape sugar made of? S. F. MILLER.

North Manchester, Ind.

[When a queen is distasteful to the bees they cluster about her, and, unless she is released, they will sting her to death—that queen is said to be "balled." Sometimes she is balled by her friends to keep the enraged bees from her—then she is "balled in a friendly way," as mentioned on page 21.

Grape sugar is made from Indian corn; the solid is called grape sugar, and the liquid is named glucose. These are not as sweet as cane sugar or molasses.

You should get a manual, and "read up" all these things; then you can understand the more advanced apiarists.—Ed.]

Honey from the Spanish Needle.

My bees are doing well; they had a good flight on Jan. 24th and 28th. Every writer should say how cold it has been this winter. When we read what Mr. Doolittle and his neighbors say about their bees, we should remember that they live in New York State, and it will not do for us in the West to govern ourselves in the same way they do. I live 198 miles south of Chicago, where it hardly ever gets too cold for bees to remain out of doors. I think that in 1880-81 there were a few colonies that did winter-kill by a careless man who let his bees remain out on some bench on the north side of his house. Bad honey is all that we dread in this part of the country for wintering bees; that is, the honey that bees gather in the late fall and never cap over. It sours and will kill the bees. The coldest it has been is 12° below zero, but it only lasted a

part of one day. Several mornings it was 10° below zero. We have had a very good winter, and our bees have the very best of honey. Our principal yield of honey is from the Spanish needle. Does it sell as well on the market as other honey? I have about 20 colonies to transfer; when is the best time to do it? They are all in good movable frame hives, but they have deep frames, and I use the Langstroth hive.

D. R. ROSEBROUGH.

Casey, Ill., Feb. 1, 1883.

[The honey from the Spanish needle will sell very well, especially if extracted.

The best time to transfer is in early spring, before there is much honey in the hives.—Ed.]

"Mason" Bees.

I send an insect, and wish to know what it is, and what its habits are. A miner discovered about half a peck of them some 12 feet in from the mouth of a coal bank. Do they usually inhabit such places? The men are much excited about them.

PETER SEARS.

Barnesville, O., Jan. 24, 1883.

[The insect is one of the "Mason" bees, belonging to the genus *Colletes*. It is a member of the large family, the *Apiaridae*, of which the hive bee forms a conspicuous part, though its habits are quite different from the latter. No one, so far as I know, ever before found them in a coal mine, but their usual nesting, or home-making place, is in the ground, where they tunnel out, a foot beneath the surface, six or eight cells, some inches long and two-thirds of an inch in diameter, lined with thin, silken membrane and closed with a cap, like a drum head.

The bees gather pollen and have been seen in considerable numbers in the flowers of squashes, cucumbers, etc., but I do not know that they collect or use nectar. They are stingless and harmless little creatures, and seem to have little fear of harm to themselves, being slow in their movements and appear to make little effort to escape.—T. J. BURKILL.]

My Experience in Wintering Bees.

I have 24 colonies in "Langstroth hives;" I changed 6 of them to doubled-walled chaff hives; the others had large boxes placed around them, and the spaces filled with chaff. The weather has been very cold for the last two weeks, and the snow had drifted entirely over some hives. I thought I had better remove the snow from the entrance, for fear they might smother. I found, in front of those packed in chaff, a large hollow space in the snow, which the heat from the bees had melted, and what bees had died were in front of the hive, on the

ground. The chaff hives were not in as good condition; they had alighting-boards fastened in front of their hives, and as some snow had blown in and some moisture run out from the inside of the hive, the entrances were entirely filled with ice. I expected to find them smothered, as the air seemed to be entirely excluded, but they were all right, and the 24 colonies are yet all right. I think I have learned a lesson; there should be no alighting-boards in front of hives in winter, as ice will collect on it to the detriment of the bees. The entrances should be large with nothing to hinder the dead bees from falling to the ground. Bees properly packed in chaff will never perish from cold; if they fail to winter, it will be from some other cause.

S. J. YOUNGMAN.

Cato, Mich., Jan. 28, 1883.

Experience of a Beginner.

A swarm came to me, a year ago last spring, and I hived them in a box hive. Last spring they swarmed and I had a frame hive all ready, but, not knowing how to manage to find the queen, we could not succeed in hiving them, and they all went off and hived themselves in another box hive, in a neighbor's yard. Now I have 2 colonies in box hives and I am at loss to know how to get the honey or what to do with them. Do you think it would be safe to take any of the honey away from them? They lived out doors all last winter and came out last spring very strong and full. I take the risk of leaving them out this winter, but how can I get any of the honey?

MRS. W. W. SMITH.

Princeton, N. J.

[Next spring some of the honey can be taken in the old way, by turning up the bottom of the hive and cutting out a little near the bottom. The best way is to transfer them to a movable comb hive, in the way recommended in your bee-manual, for, of course, you have one. No one should think of getting along without such at hand to refer to at all times.—Ed.]

Winter in Kentucky.

The winter in Kentucky has been a very changeable one; the mercury frequently changing from 15° to 60° within 24 hours, and as often as 4 times per week, yet the bees apparently are wintering well. I have 90 colonies on the summer stands and think they will come through all right.

J. T. CONNLEY.

Napoleon, Ky., Feb. 3, 1883.

Bees are Wintering all Right.

The bees are all right; but they have had no flight since the beginning of November, now almost three months. There are very few dead bees on the bottom boards, not averaging over $\frac{1}{4}$ of a pint, per colony. This is now the tenth winter's experience for my system of wintering bees, and have not lost a single colony, all these

winters in succession. This, I think, proves my system correct; especially when we take into consideration that we are 2,200 feet above the sea level, and that our winters are cold and prolonged.

H. H. FLICK.

Lavansville, Pa., Jan. 31, 1883.

Thirty Degrees below Zero.

The weather is a little more comfortable now—still there is no thaw or rain—we have had nothing but dry, cold, snowy weather. On Tuesday, Jan. 24, at 6 a. m., the mercury was down to 30° below zero. How is that kind of weather for bees on the summer stands in box hives? If they live, cold will not kill them, will it?

J. A. MORTON, M. D.

Bethel, Maine, Feb. 2, 1883.

King's Cure-all as a Honey-Plant.

I send you some pods of seed of a good honey plant. What is its botanical name? We call it "King's cure-all." It blooms a little on a single stalk, the first year; the next year it throws out branches, growing 6 or 8 feet high, and blooms about the middle of July, and continues blooming till frost. The flower is a small cup with a lid over it, keeping out the sun and rain. The bees work on it early and late.

S. P. SOWERS.

Dunlap, Kansas.

[The plant seems to be *Scrophularia nodosa* ("Figwort," Simpson's Honey Plant). The fruit capsules are more densely produced than is common with the above species, but it cannot be far different, and there is no near relative known to me to which it may be referred. It is, probably, the variety known as *Marilandica*.—T. J. BURRILL.]

Catnip as a Honey Plant.

Since honey plants are of the utmost importance to successful bee-keeping, I would say that I agree with Mr. Elliott (see page 69), as far as he goes, about catnip. We have, in our city and vicinity, quite a good deal of catnip growing. Three years ago I gathered some 6 lbs. of seeds and sowed it on waste places, and I noticed bees working on catnip all-day long, and if they found no honey in it, they would not visit it. Should I ever need to plant much for honey, I would plant considerable catnip.

H. S. HACKMAN.

Peru, Ill., Feb. 6, 1883.

Medicinal Qualities of Honey.

I was much interested in an article in the BEE JOURNAL of Dec. 27, page 818, from Mr. Luther Corey, of York-shire, N. Y., in regard to the medical qualities of honey. The thought suggested to me was, that honey taken from different kinds of flowers does not contain the same medicinal qualities. As physicians use the roots, bark, leaves and flowers of different kinds of honey-producing plants, shrubs and trees, and each kind for a different disease, so may the honey

taken from each kind of plant, shrub or tree, be a better medicine for some one disease than for all diseases. The buckwheat honey may be a better medicine for one kind of sickness, while that taken from linden will be better for some other kind, and so on, with all the different kinds of honey. I think if we will be careful to keep the different kinds of honey separate, and place it in the hands of medical and scientific men for investigation, it may result in good to producer and consumer.

NELSON PERKINS.

Princeton, Ala., Feb. 3, 1883.

Bees have the Dysentery.

Please answer through the BEE JOURNAL, "what must I do to save" my bees? They have the dysentery, and are wasting away very fast. I fear they will all die. I should like to know from bee-men if there is a remedy? It is a general complaint about here. I have been watching the BEE JOURNAL for a remedy, but have not noticed anything yet. I have 40 colonies, 9 in box hives. They all appear to be alike afflicted.

B. HELPHREY.

Utica, O., Feb. 3, 1883.

[Give the bees some good capped honey, over the frames, and a cleansing flight as soon as the weather will permit.—Ed.]

Bees Confined 80 Days, but Doing Well.

My bees are doing well; they have been in winter quarters 80 days, and each colony has eaten from 1 to 3 lbs. of honey. I weigh them every month; the comb in some of the hives is getting moldy; is it injurious to them?

F. A. GIBSON.

Racine, Wis., Feb. 8, 1883.

[Mold is not injurious to bees; leave it to the bees, and when the weather will permit, they will surprise you by their dexterity in cleaning it up.—Ed.]

The California Apiculturist.

Has the *California Apiculturist* ceased to exist? I have received no number of it since November, 1882!

K. ERCANBRACK.

Watsonville, Cal., Feb. 1, 1883.

[As we have not received it since November last, we expect it has been numbered with the *dead* bee papers—and "their name is legion."—Ed.]

The Winter in Canada.

We have a very severe winter, with many storms, but, to my mind, it is the best winter I ever saw for a good honey season to follow. There being no frost in the ground, the grass and wheat are growing under the snow. Last year, there being no snow, the ground was frozen everywhere; what was left of white clover was very weak or came from seed the previous summer. Upward ventilation is entirely contrary to my reasoning, and the instinct and practice of bees. The

first thing every swarm does is to plaster every crack except the entrance, which is always below the comb. But whoever heard of bees removing the propolis to cause a draught through the hive for winter. I am satisfied upward ventilation is wrong; I have studied it for 3 years, and I fail to reason out such treatment. People even in Montreal (which is about the same as Dakota or Manitoba), winter bees safely, leaving the top well sealed and raising the hives $\frac{1}{2}$ inch from the bottom board.

CHARLES MITCHELL.

Molesworth, Ont., Feb. 2, 1883.

What to Plant.

My bees, are to all appearances, wintering finely. I put into the cellar on Nov. 2 and 3, 176 colonies of my own, and 1 belonging to a friend, all Italians. I have made arrangements to start another yard in the spring, about 6 miles from here. I have bought 80 acres to sow for honey and I would be thankful for your opinion as to what is best to sow, all things considered. It is low land, that overflows about 2 out of every 3 years. There is lots of basswood, and all kinds of timber, close by; such as soft and hard maple, willow, elm, box elder, etc., with high bluffs within one mile on the north or south, covered with goldenrod and various other flowers. I intend to make bee-keeping my future occupation and I want to start right. From what I have seen of sweet clover and motherwort I think they are well worth cultivating for honey. I believe that to get the right kind of bees is no longer a question; all that is required is to carefully breed from those containing the most desirable qualities. I do not allow drones to fly from any hive that does not come up to the highest standard. I kill all queens that produce one or two banded workers, or very cross ones, and replace them with good ones.

WM. LOSSING.

Hokah, Minn., Jan. 30, 1883.

[Sweet clover is the best honey plant we know of, for such a location.—Ed.]

Iowa State Convention.

I second Mr. Sorrick's motion for a "Bee-Keepers' Convention" to organize a State Association, during the Fair week. Allow me to suggest that Mr. Sorrick issue a call for said meeting. If those interested in bee-culture will indicate, to the board of directors, the classification and amount of premiums for this department, I have no doubt it will receive a favorable consideration, as they are ever ready to lend "a helping hand" to develop any interest that is a benefit to the citizens of our State.

E. R. SHANKLAND.

Dubuque, Iowa, Feb. 5, 1883.

Syrian Bees.

The new Monthly BEE JOURNAL is here, and a neater, more beautiful, well-printed monthly we never have seen. It glows with rich contributions from the best writers on scientific bee-culture. I notice in the Weekly BEE JOURNAL, page 59, a desire to know

the markings of Holy Land bees. If the writer ever has any occasion to manipulate them, it will not be difficult to identify them, for they will be very apt to make a lasting impression, never to be forgotten, for they are more treacherous than a Modoc Indian; the minute you open the hive they hoist the black flag, and start on the war path. They are good honey gatherers, and go upon the principle "that he who does not look out for his own household is worse than an infidel." They are as quick as lightning. I am glad that the BEE JOURNAL is talking to so many bee-keepers in the world; some of the old fogies are getting the scales from their eyes and are discarding brimstone to some of the most useful insects that a wise creator ever bestowed.

F. H. FINCH.

Sharon Centre, O., Feb. 1, 1883.

Frost in Bee House.

I looked at my bees yesterday, and they are all in fine condition. I have them in a bee house; the thermometer has stood between 26° and 34°, all winter. There is hoar frost in the inside of the house, all round, will it do any harm, when it gets warm, to melt the frost? Would it be good to sweep off the frost of the walls and sweep it out? Would the sweeping annoy the bees too much? I have chaff cushions on. Please let me know through the BEE JOURNAL.

GEO. KEMP.

Navan, Ont., Jan. 27, 1883.

[The only remedy we can suggest is to raise the temperature. Had it been kept at from 40° to 45°, as we have so often advised in the BEE JOURNAL, the frost would not have invaded your bee-house. To remove it now, by sweeping, would cause a disturbance, and when it melts it will create some dampness, and the result may be detrimental to the bees.—ED.]

A Request.

In one of Mr. Doolittle's invaluable articles on "Producing Comb Honey," page 229, he says: "The old colonies losing their queens by their going with the new swarms, are allowed to rear their own queens, as (after thoroughly trying the plan of) giving each colony a laying queen immediately after swarming, has not proven a success with me." I respectfully ask Mr. D. to favor us with some particulars on this point, and the reason why the plan was not successful.

J. W. MERIFIELD.

Penn Yan, N. Y., Jan. 24, 1883.

Bees in Cellars all Right.

I have devoted considerable time today in looking over the last volume of the BEE JOURNAL. I have it all bound together, and prize it very much for future reference. We are having a severe winter, especially since the new year began. The thermometer has been to zero and below, nearly every day during the past month; and it has been down as low

as 32° below. Some are losing their bees, where they are not protected. I have mine in the cellar, and all seem right except one, which shows some signs of dysentery. The temperature of the cellar is 40°; is that too low?

J. W. SANDERS.

Le Grand, Iowa, Feb. 2, 1883.

[We prefer to have the temperature above 40°; that is the lowest limit for it; keep it above that.—ED.]

Bees Wintering Finely.

I like the BEE JOURNAL very much; indeed, it has become a necessity, and I would hardly know how to get along without it. My bees are wintering finely, notwithstanding the extreme cold. I have all but 7 of mine in the cellar; 45 in all.

DR. H. J. SCOLES.

Knoxville, Iowa, Jan. 25, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

New Catalogues and Price Lists.

The following new Catalogues and Price Lists are on our desk:

Bees, Queens and Apiarian Supplies.—Dr. J. P. H. Brown, Augusta, Ga.
Bee-Keepers' Supplies—Alfred H. Newman, 923 West Madison Street, Chicago, Ill.

Italian Bees—Rev. E. L. Briggs, Wilton, Iowa.

Apiarian Implements, Italian Bees and Queens—Paul L. Viallon, Bayou Goula, La.

Bee-Keepers' Supplies—Chas. F. Muth, 976 and 978 Central ave., Cincinnati, O.

Bees, Queens and Bee-Keepers' Supplies.—E. T. Flanagan, Belleville, Ill.
Seed Catalogue.—Vanderbilt Bros., 23 Fulton St., N. Y.

Italian Bees, Queens and Apiarian Supplies.—James B. Mason, Mechanic Falls, Me.

Apiarian Implements.—L. E. Welch, Linden, Mich.

Bee-Keepers' Supplies.—Merriam & Falconer, Jamestown, N. Y.

Implements for the Apiary.—Chas. J. Van Eaton, York, N. Y.

Bees and Queens—W. A. Hammond, Richmond, Va.

Mr. A. E. Manum, Bristol, Vt., has sent us samples of one-pound, two-pound and half-pound sections. They are made of white wood, and the workmanship is superb.

Convention Notices.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.

Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nelle's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Articles for publication must be written on a separate piece of paper from items of business.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

A Severe and Cruel Winter.

The snow storms, blizzards and very severe weather of the past five or six weeks, has now given way to a less rigorous atmosphere, accompanied with rain, and the results are, destructive floods and inundations all over the country, by the rapid rising of the great rivers and their tributary streams. The reports for weeks have been about delayed and blockaded trains, terrible snow drifts, with the temperature so cold that steam could not be maintained, and hundreds of men and thousands of animals have perished. Now, the song changes—of those animals that are left many more are drowned with inundations, and men are robbed of their habitations; thousands being made homeless and destitute.

This state of things not only obtains in America, but also in Europe. England has been visited by storms more severe than for many years; her coasts have been lashed with the furious waves; many of her stately oaks and pleasure bowers have been leveled to the ground, and much of her shipping has been destroyed. On the European continent, floods and storms of unusual severity have destroyed and laid waste many large tracts of country, and the cry for help from those made homeless and destitute, ascends to Heaven from thousands of those who, before this calamity, were in pleasant circumstances.

One of our exchanges, speaking of the terrible disasters thus far, asks: "Is 1883 to be a year of calamities?" Well, surely, it seems already to have made a terrible record in that line,

including fires, floods, snow-blockades, sheet-storms, blizzards, shipwrecks, train disasters, financial failures and earthquakes.

Of course, the bees have suffered as well as other stock. For nearly two months, here in the North, those wintered on the summer stands have been imprisoned by storm and tempest; and, finally, their hives were enveloped in an icy winding-sheet, or else carried away on the wild waste of waters, and the poor bees drowned by the mad element, if they still survived the rigors of the Northern wintry blast.

In some places, disease has set in, and many may yet die of that fearful bee malady—dysentery.

This winter will try, to the utmost, all kinds of out-door wintering. What the final results may be, can, as yet, only be conjectured. Those in more favored localities, where the floods have less power, will be able to have a "flight" soon, and the threatened damage by disease may be averted.

Many already have asked us, What effect all these troubles will have on the bee industry? We reply: Just the same as it does on the farmer, manufacturer, merchant and stockmen. The floods have destroyed the stock of thousands of merchants, stopped the "busy wheels" of manufacturers, and carried away thousands of dollars worth of their property. Will they become discouraged and give up? No! with redoubled energy they will start anew and retrieve their losses!

Because the storm king has destroyed thousands of vessels and many cargoes, will the mariners forsake their calling? No! but with dauntless courage they will pursue their labors and bid defiance to the elements.

Mr. L. James, on page 111, says that the fruit trees, in his neighborhood, are nearly destroyed, and the outlook for fruit is discouraging. Will the fruit culturist cut down his trees,

"cast them into the fire," and look for some business that has no drawbacks? No! he will plant again, watch, cultivate and hope for the best!

Millions of acres of land, by the recent inundations, have been robbed of fences and buildings, and many winter crops destroyed—will the farmer cease to plow and build barns and houses for his cattle and herds, and repair the damages? No! Tomorrow's sun will illumine the skies, earth will smile in gladness; her fields will soon be covered with verdure, and her gardens with flowers; luscious fruit will gladden the heart of "the sons of toil," and fill the pockets of those whose dauntless courage impels them to labor for the desired end!

The bees have been compelled to *fight for existence*, with disease on the one hand, and winter's fiercest blizzard, ending in floods and tempests, on the other. Is it any wonder that, in this unequal contest, they have suffered to a greater or less extent, governed by their location and the surroundings, together with the care and protection afforded them by their keepers? Instead of being discouraged over the situation, we should feel that our sympathies are needed by the poor bees, who have been thus tortured, and beset on every side with warring elements in a mad career of desolation. We should admire their pluck, energy and endurance, instead of being cowardly enough to try to find an entrance for ourselves to that *dungeon* over whose portals are written the stinging motto—"Blasted Hopes." There are no such words as "blasted hopes!" in the vocabulary of men of true worth. Reverses only stimulate "progressive men" to further diligence.

When the fruit grower, the farmer, the merchant, the sailor and the manufacturer become discouraged and "give up the battle," it will be time enough for the bee-keeper to *think* about being discouraged! *Until then,*

give no heed to such a bugbear as "Blasted Hopes," but, by perseverance, pluck and energy, *hold on*; for the average years, for bee-keepers, make as good a showing for "bees and honey," as for any business a man can engage in.

The Forncrook Patent Section.

The following, from Mr. Baldridge, is due as a correction, concerning the illustrations given in his previous article on this subject:

I regret exceedingly to find the wrong cut used in the fourth illustration, on page 72, in my article on the Forncrook Patent Section. The following cut

is the one used, which correctly represents the section covered by the Forncrook patent; the one I desired to be used is the following:

which shows a one-piece section without the recesses or passage ways for the bees, and likewise without the "longitudinal groove." This style of one-piece section is public, and not private property; so are all sections having 2, 3 or 4 pieces. The one-piece section, having a top as wide as the sides, and a bottom so narrow as to give ingress and egress to the bees, is also public, and not private property; in other words, there is no style of section, whether in one, two, three or four pieces, that is private property (that is, covered by a patent), except the one style made precisely like the section shown in the first cut in this article. Now, I trust the explanations will not be misunderstood.

In the preparation of my article, as it appears on page 72, I did not dream that an enigma would be attached thereto, to wit: That the one-piece section was invented by Mr. Forncrook, that it has been patented to him, and that it would be dishonest and fraudulent to evade said patent. At this date, I have no proof that Mr. Forncrook was the first and original inventor of the one-piece section "of any description," nor that his patent covers anything of the kind; nor that it is wrong, dishonest or criminal to evade anybody's patent, by making what is or should be public property? What right has Mr. Forncrook or any one else to frighten bee-keepers, by threats or otherwise, from making, using or selling property that already belongs to them? Why should bee-keepers pay a tribute of \$1 to \$2.50 for each 1,000 one-piece sections to Mr. Forncrook, on what is public property, or on what they have a perfect right to get elsewhere at lower figures?

M. M. BALDRIDGE.

We desire neither to add to nor take from our editorial note, appended to

Mr. Baldridge's article, on page 73. We believe the position there taken is invulnerable. The patent has been issued to Mr. Forncrook, and that, too, after a prolonged and tedious fight. As to its invalidity, let the courts of law decide, as is suggested in the following from Prof. Cook:

DEAR MR. NEWMAN:—I send you the following article which I wrote to the N. Y. *Tribune*, and I hope you will give to our friends in the AMERICAN BEE JOURNAL:

Perhaps no class has suffered more from imposition in reference to patents than bee-keepers. The whole art, as practised to-day, rests on the use of inventions. Take away our hives, sections, extractors, and foundation machines, and apiculture would be bereft of all that gives it prominence. Unscrupulous persons may invent attachments to some of these valuable instruments, which attachments may be wholly worthless, and, in combination with other inventions which have long been in use, get a patent. Then by threat they induce those who use the article, often with their invention wholly omitted, to pay them money.

The sale of the Mitchell hive and the collection of money by threats of prosecution, extensively carried on by its inventor, illustrates the point, and it seems to me that we have just now a case exactly in point in reference to the one-piece sections. I know of several dealers who sold from 1,000 to 500,000 of these the past year. Now, if bee-keepers are forced to pay \$6.50 or \$7.50 per 1,000, when, with no patent hanging over us, \$4.50 per 1,000 would be deemed a good price, we see a serious wrong is committed, unless, forsooth, the patentee has a clear right to his claim.

In 1877, I used one-piece sections with transverse cut to enable me to bend them, with a recess on one side cut by a chisel, made U-shaped. At the same date, many were selling dove-tailed sections with a longitudinal groove in which to insert foundation. In 1878 Mr. Lewis, Watertown, Wis., made one-piece sections, with oblique transverse cut, the recesses such as I made the previous year, and longitudinal groove. May 19, 1880, James Forncrook, foreman in Mr. Lewis' shop, applied for a patent on just this style of section. The patent was secured.

In a prosecution of Mr. Lewis for infringement in the summer of 1881, Mr. Forncrook, at first, as I understand, failed to make a case, but, upon a rehearing, won on the ground of the recess, on the side of the section, which permits the bees to pass up into the section. These recesses I cut one year before they made the section at all. Now, as I understand Mr. Forncrook's patent, it is a combination. Unless a section is in one piece, with oblique transverse cuts, the longitudinal recess, and the longitudinal slit for foundation, it does not infringe on his patent. Omit any single feature and we do not trespass.

Practical suggestions: Believing that Mr. Forncrook has no rights in this matter, I suggest that a friendly suit be brought to test the question. Each bee-keeper who uses sections can afford to pay \$1 to bear the expenses of the suit, and then save much money. Again, if I understand the matter, any one can manufacture a one-piece section, with the recess and transverse cuts, if he only omit the longitudinal groove, which is really of no importance, and run no risk at all. I can see no equity in our paying \$2 or \$3 for every 1,000 sections that we use to Forncrook, when he really has done nothing to give us this important invention.

A. J. COOK.

Lansing, Feb. 6, 1883.

Prof. Cook's "practical suggestion" is a good one, and is the only *honorable* way to test the matter; that is, by a friendly suit to decide it, in a legal way. Until it is decided, however, by legal means, an *evasion* of the rights of the patentee is a *crime*, recognized by law as such.

We do not propose to occupy many pages of the BEE JOURNAL to discuss a matter which must be decided by law; we will, however, give the following, from Mr. E. J. Scofield on the subject:

I have just read the opinion of M. M. Baldridge, on page 72 of the BEE JOURNAL, in which he desires to set aside the patent of James Forncrook, or dodge it in some way. The two-piece section is, I think, a gross infringement on the Forncrook patent; it may not be in the eye of the law, but, nevertheless, it is a piece of wood for storing surplus honey, with transverse angular grooves, to be bent together in the manner of the Forncrook section, with the fourth piece to be dentated at both ends. He leaves out one of the transverse angular grooves in the patent section; otherwise it is an exact copy of the patent section. I am no lawyer, but I like to see honor and justice bestowed, where it is due. A section is being manufactured now, exactly like the one illustrated by Mr. Baldridge, at a lower price per thousand, but I prefer the one-piece, for two reasons: First, it is a handsomer package than the two-piece one, and it is stronger. Secondly, I would not use the two-piece section and thus encourage its manufacture. I was all through the factory where this section is made, as well as through the factory where the Forncrook section is made, about two weeks ago, and talked with the proprietors of both establishments. The proprietor of the two-piece box admitted that the two-piece section was intended to evade the Forncrook patent. James Forncrook has spent both time and money to secure what was rightfully his, in the first place, as all bee-keepers well know, who have read the BEE JOURNAL for the past five years. I will copy the following from page 10 of Forncrook & Co.'s price list for the year 1880:

"A word of explanation. As bee-keepers, no doubt, think it a little strange that we advertise and claim to be the inventors of the Boss One-Piece section, heretofore called the Lewis section, we think it necessary to explain the situation. I worked for G. B. Lewis, and Lewis & Parks, as their foreman, for the past 11 years, and in the spring of 1878, I invented the Boss section. On the first of October, 1878, the co-partnership of Lewis & Parks was formed, and they, thinking it a good thing, made an application for a patent without my knowledge or consent, thinking to get a patent before I would know it, and then let me whistle. I mistrusted what they were up to, but said nothing to them about it, but wrote to a lawyer in Washington, asking him if there was any way to find out? He wrote me that the only way to find out and prevent them from getting a patent, was to make an application myself. I made an application and found that they had also, and would undoubtedly have had a patent allowed them in a short time. Then it was put into interference, and we had to prove who was the inventor, which I proved to the satisfaction of the Examiner in the Patent Office, and the commissioner of patents awarded me priority of invention March 12, 1880. Now, after they find they cannot get a patent, they are trying to prove that it is an old thing, and not patentable. I will leave it with bee men to judge whether it is new or old. I propose to have a patent on it now, as it has gone so far, but probably I should never have applied for a patent if Lewis & Parks had not tried to beat me out of it.—JAMES FORNCROOK."

Now, I think it is our duty, as bee-keepers, after all that has been done about it, not to encourage an infringement; if the one-piece does not suit us, let it alone, and use either the dove-tailed or nailed sections. I used to manufacture dove-tailed and nailed sections for my own use and my neighbors at \$8 per 1,000; I have the machinery now, but will make no more; for I shall use the one-pound, one-piece section as long as I can get it, made of white basswood, planed and sand-papered on outside and edges for \$6 per 1,000.

I have no axe to grind; no interest in bee fixtures of any kind; Forncrook & Co. are no personal friends of mine; I never saw them until about two weeks ago, when I went there to see about getting supplies, etc., for the coming season; but when I see a fellow bee-keeper, as Mr. Forncrook is, in danger of being defrauded of his rights, I want to let my fellow bee-keepers see how it looks to me.

E. J. SCOFIELD.

Hanover, Wis., Feb. 3, 1883.

To the above may be added the following, which takes still another view of the matter:

I know the BEE JOURNAL is not published for the discussion of patents in general, but the article from Mr. Balldridge, on page 72, may mislead, and needs correction. Any person

making use of a patented invention, in whole or in part, without the owner's consent, is infringing, and lays himself liable; even if a person wants to make an article for his own use, it is not allowed, and a patent cannot be evaded by simply leaving off a portion of the invention, as stated by Mr. B. If it could, our patent laws would be no protection to an inventor. I think the two-piece section is an infringement on the Forncrook patent, but the question is: Can the Forncrook patent be lawfully sustained? I think not. Mr. A. I. Root, on page 98 of *Gleanings*, 1882, says: "Before us is a copy of a patent, granted in 1874 to H. W. Hutchins, East Livermore, Maine, for a plan of making boxes of one-piece of wood, precisely like the Forncrook sections, even to the V-shaped groove, dove-tailing the ends, and all. The drawings make it so plain that it is difficult to conceive that Forncrook's was not copied from it."

I am not personally acquainted with the party manufacturing one-piece sections; but I endorse what the editor says on page 73, that the inventor is entitled to a reasonable reward for bringing the section to the present state of perfection, but I do not like his advance on the price of sections over what others can make them for, just because he has a patent on them. A. J. HINTZ.

Lamont, Ill.

The assertion that the price has been increased since the issuance of the patent, is not sustained by the facts. By consulting old price lists, on file in this office, we find that they were sold before the granting of the patent at from \$1 to \$2 higher than the price now asked by the patentees, and at the same time they are made vastly better.

Before the patent was issued we were summoned by Messrs. Lewis & Parks before a commissioner, directed by the Patent Office, and for 3 days we were questioned and cross-questioned by opposing lawyers, and did all we could to defeat the patent. With all the facts obtainable, the patent was issued, and now should be respected by all law-abiding citizens.

There are points in all four of the communications that we do not approve, but it is unnecessary to state them—the whole matter must be decided by the technicalities of law, and it will be useless for us to discuss a thing we have no power to decide. "To the Law and to the testimony," must the appeal be made—that is authority, decisive and final.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75.

The Queen that Did Not Come.—In the Weekly BEE JOURNAL, page 54, Mr. O. E. Cooley, while trying to prove that "bees move eggs from one cell to another, mentioned the fact that he had been waiting for a queen for three years from Mr. Alley, but it did not come." This allusion to a business transaction, so woven into the article, passed unnoticed till it was published. In justice, now, we admit the following from Mr. Alley:

MR. EDITOR:—Please allow me place in the BEE JOURNAL to say, in reply to the article of Mr. Cooley, that his claim has long been in dispute. I am not satisfied that he did, or did not, send me the \$3 he claimed. However, rather than do him an injustice, the amount was sent him sometime before his article appeared in the JOURNAL. HENRY ALLEY.

W. ham, Mass.

The BEE JOURNAL has nothing to do with settling disputes over business complications, and we hope not to be troubled with any more of such.

Many bee-keepers, as well as thousands of others, have been swindled by some bogus "brokers," hailing from this city. It is the old "confidence game" played over again. Some of the "certificates" have been sent to us, asking if we can collect anything on them. Of course, they are worthless, and we would, again, warn all our readers against sending money to irresponsible persons, for anything whatever. The parties we refer to have been doing [a cheating] business under the names of Flemming & Merriam, R. E. Kendall & Co., Charles J. Henri & Co., Cudworth & Co., and Bennett, Koltzman & Co. The principal man, Flemming, has gone to Canada with many thousands of dollars of booty.

Size of Standard Langstroth Hive.—Since reading the article on the standard Langstroth hive, I have made considerable inquiries, and I can find no two factories making them of the same dimensions. If there is a standard size it ought to be duplicated and everywhere used of the same size. CHARLES NORRIS.

Traverse City, Mich.

It is to be deplored that so many will vary the size of a frame or hive from the standard size, just for a simple notion. It is high time for a reform to be made in this particular, and a standard size of frame be adopted and unvaryingly adhered to.

Several catalogues are received, but, our pages being crowded, notice of them is deferred until next week.

For the American Bee Journal.

Run for Right Race of Bees.

That coming bee, we want to see,
Coming to near perfection;
Of true specific, scientific,
Well-devised selection.

In choice of kind, and use of mind,
In age of vast progression;
'Tis now behooved, to have improved,
Yet genuine succession.

That bee that we, can all agree,
Shall come to be the leader;
Take all the sorts, home and imports,
We pray, great chieftain breeder.

Italians bright, may well delight,
Gold dollars indicating;
Then strong, plain blacks with well-filled sacks,
Deserve not underrating.

Smart Cyprians, too; wonders may do,
Of vast, prolific nature;
And Palestine may much combine,
Of extra valued feature.

Albino pure, or, not so sure,
Cross'd, mix'd, or various races;
From all select, to main effect,
Suited to sundry places.

Knowing and wise; study, devise,
To have petition granted;
And being about, beyond a doubt,
The special bee that's wanted.

To winter live, and summer give,
Large stocks and lots of honey;
Pure nectar piles, and fancy styles,
Denoting piles of money.

Breed beauteous rings, and gentle stings,
But, long and short, that's of it;
All else aside, the strain provide,
That's bound to bring the profit.

When ye succeed, to meet the need,
Canadian or ye Yankee;
The race well run, the prize is won,
Aptists all will "thank ye."
Toronto, Canada. S.

For the American Bee Journal.

Eggs or Larvæ, Which?

G. M. DOOLITTLE.

On page 54 of the BEE JOURNAL, for the present year, Mr. O. E. Cooley tells us that bees remove eggs from one cell to another, and then states why he believes they do so, giving the negative side as proof of his position. There are other ways by which the colony might have obtained a laying queen, besides the one he gives, such as a queen entering the wrong hive, or a small swarm with a queen, going into it, etc.; but, as that is not the object of this article, I will not go into detail.

He says the "bees must have moved an egg;" I take it for granted that, if the bees moved anything, it was a larva. That bees do sometimes remove eggs I admit, but they are not apt to do so, where there are larvæ at their disposal, as there was in the case given by Mr. Cooley.

To illustrate: A few years ago I had a colony which was "bent on swarming," and I was equally "bent" on their staying where they were. They had come out twice, and I had put them back, cutting out the queen cells each time. After staying five days they came out again, and while they were out, I cut out all the queen cells, queen cups, and everything I could find that might look like an em-

bryo queen cell, when they returned. When about half of the swarm had entered the hive, out came two swarms from other hives, and instead of alighting, they simply passed out of their hives and went in with this returning swarm. As the queens to both of these last, had their wings clipped, they were returned to their old hives, and the bees allowed to stay with those I had determined should not be hived as a separate swarm. I put on extra surplus room, so that the three swarms could work to advantage, if they saw fit so to do. However, they did not "see fit," for at 10 o'clock the next morning, all came out in the shape of a rousing swarm (three swarms in one), and so I concluded to give them an empty hive. Upon going to the old hive, I counted more than 250 queen cells, upwards of 50 of which had larvæ in them. More than 25 had eggs in them, which were all but one or two deposited there by the queen; those one or two being carried there by the bees. The larvæ, which were transferred, were from one to four days old, I should judge by their appearance, and were plentifully supplied with royal jelly.

I could give several other instances where larvæ have been removed for queen-rearing. Where bees have access to both eggs and larvæ, and a removal of either is considered necessary, my experience proves that they nearly always select a larva; this being in accordance with the accomplishment of their object, which is to get a queen in the least possible time.

For the American Bee Journal.

Clipping the Wings of a Queen.

G. W. DEMAREE.

At the close of each volume of the BEE JOURNAL, when it has been arranged and bound in convenient book form, I find it quite entertaining to review its pages and note what has been established as truth, and what still remains theory. The well arranged index at the close of the volume makes this a very easy and pleasant task.

To the readers of the middle and southern sections of our country, the subject matter pertaining to the wintering of bees, is simply colossal in magnitude, enough to make the "head swim." My insatiate greed for "bee literature," however, has induced me to wade through the whole of it, cellars, chaff, sawdust, pits, caves, clamps, *ad infinitum*. Just think of crowding the little fellows so closely that their legs stick out of the doors and windows. It occurs to me that if there is no cases of bee murder, there is much involuntary bee slaughter going on in many parts of the country.

But, at this time, I wish to notice the well-nigh universal practice of clipping the wings of the queens. In all of volume 18 not a single voice except the emphatic protest of Mr. James Heddon, as reported in the proceedings of the Michigan Convention, has been raised in defense of

the inalienable rights of the proudest and grandest of God's little creatures—the queen honey-bee. Mr. G. M. Doolittle says that "wings are created to fly with;" yes, but is that all? Are they not a "cover" to her body, her beauty and her glory? If there was nothing but the merest sentimentality in the objections I raise to the wholesale chopping off of the wings of beautiful queens, the plea of Prof. Cook, Dr. Miller and others that they could not keep bees without clipping the wings of the queens, is sufficiently "set off" by the success of Mr. Heddon and others who do not clip the wings of their queens.

One of the defects of our bee literature is, that each writer sets forth his dogmas as though his locality and surroundings were the same as every other place on the earth. I think I can see why Mr. Doolittle can get along with clipped-wing queens, and also, why I and others operating in a different climate to his, cannot get along so well with them. From long observation I have found that bees never supersede their queens during the period which intervenes between the time breeding ceases in the fall and its commencement in the spring, and they rarely ever supersede them during the early and late honey harvests, simply because, in the latter case, an attempt to do so always results in a swarm. Of course, queens sometimes die during those periods, in which there is no inclination on the part of the bees to supersede them.

Well, in a climate like ours, there is generally a period of about six weeks, say from the middle of July to the first of September, in which the dry hot weather parches the flowers, and the bees find but little to do in the fields, and being strong in numbers they are ready to cut all sorts of fantastic tricks. They will learn how to cut holes in the quilts, nibble away at the furniture in the hives, cut to pieces sheets of foundation, "ball" and supersede their queens, especially if the queens are getting old, or are maimed in any way. I do not remember of ever having had a queen to survive two whole seasons whose wings had been cropped in the usual way.

Better success, however, can be had by trimming the inside of one pair of the queen's wings, preserving the original shape of the wings, taking off just enough to bring the queen down when she attempts to fly. I now have a queen, of good old age, whose wings were trimmed in this way when she first commenced to lay. To perform the operation, you pick the queen from the comb on which she is found, holding her wings between the thumb and fore finger of the right hand, now place her body across the fore finger of the left hand, bringing the thumb gently down upon her head and thorax—you now have her in position—then take a small pair of shears and trim off the inside of one pair of her wings, preserving the original shape of the wings, and you have done a scientific job. With a queen manipulated in this way, the inquisitive workers will rarely ever find fault.

But, right here I wish to suggest what I have never seen a hint of in print, or heard mentioned by any one, viz.: That if the honey bee is not an exception to all the rules of past experience, as applied to winged domesticated animals—our domesticated fowls—the continuous clipping off the wings of the queens, thus depriving them of their natural use and health-giving exercise, as well as the interference with the circulating life-giving fluids of the body, will as certainly, in process of time, enfeeble the “wing power” of their progeny, as the same process of treatment has changed our domestic fowls from “birds of the air” to their present toddling condition. Most likely there are some who will be ready to laugh at such an idea, nevertheless, causes will continue to produce their effects all the same.

Dr. Wm. M. Rogers, of Shelbyville, Ky., from whose keen perception nothing escapes, pointed out to me, several years ago, unmistakable evidence of clumsiness on the part of our “carefully bred bees,” seen in their proneness to trip and tumble on their backs, and their spasmodic struggles to right themselves when rushing out of the hives during a brisk honey flow. Their lofty tumbles on the alighting-board is not only amusing and ludicrous to behold, but is in striking contrast with the little lithe iron-gray bees that plied in and out of my box hive 20 years ago. In every attempt to breed for good points, “wing power” should stand at the head.

Christiansburg, Ky.

Mahoning Valley Convention.

The annual meeting of the Mahoning Valley Bee-Keepers' Association was held at Berlin, on Jan. 19 and 20. After the reading of the minutes of the last meeting (which were approved), the president, Mr. L. Carson, appointed the following committee on bee fixtures: Mr. H. A. Simon, Mr. Mattoon and Mr. Eadler. In the absence of the secretary the chairman appointed H. A. Simon, Sec., *pro tem*. The president then announced the meeting open for discussion, and the first question was: What is the cause of dysentery?

Mr. Simon inquired under what condition they got it.

Mr. Mattoon: I have noticed a good many dead bees on the bottoms of my hives, and a bad odor; it may be that they are too damp.

Mr. Simon: I would use syrup from good sugar; I think it a good remedy.

Mr. Carson: A few years ago my bees became affected with the dysentery. I carried the bees into the house and fed them melted sugar, warmed them up thoroughly, replaced them on the stands, and did not lose any.

Mr. Mattoon: I give my bees a flight once in the winter. I place one hive at a time in a large hot-bed, and give them a good flight; then cover the glass all over, but a small place just over the hive, and they will all go in and losses by this process are few.

Mr. Newton applied sulphur in small quantities, by raising the blanket and scattering it over the bees. He has used salt with good results.

Mr. Simon thought dampness and close confinement the cause of dysentery. A remedy for this difficulty was proper ventilation and close attention to the bees.

Mr. Carson thought that the Italians were preferable to any other; they were strong, vigorous workers; the queens were prolific, and they are generally easy to handle.

Mr. Newton thought one or two hives enough for an amateur to commence with. He should not put too much money in a business he is not familiar with.

Mr. Simon considered five or six none too many; a man would have to pay considerable attention to that many, and would take better care of them.

Mr. Carson said, it will pay to plant pasturage for bees; sow sweet clover (*melilot*); fig-wort has great merit. I would advise the planting of basswood and the golden willow along the highways.

January 20th, a short forenoon session was held, discussing the management of bees, in general.

The inclemency of the weather kept many from attending the afternoon session; the election of officers for the following year resulted as follows: President, Leonidas Carson, Milton; Vice-President, H. A. Simon, Lordstown; Secretary, E. W. Turner, Newton Falls; Treasurer, Geo. Carson, Berlin, O.

Mr. G. A. Newton, of North Benton, O., exhibited and explained the working of his drone trap, for catching black or hybrid drones.

Mr. Eadler exhibited some of Gray's bee feeders.

Mr. Frank King showed some of his improved wired frames for extracting.

Mr. Simon said, if honey is to be shipped it is necessary to use separators.

Mr. Carson: I would advise all bee-keepers to try and sell all their honey at home, even if you sell for 2 cts. per pound less. I consider it one of the healthiest sweets, and excellent for canning fruits. We use it in our family, and never have any fruit spoil.

Mr. Simon suggested that we create a market for extracted honey at home.

Mr. Simon said, I moved some 30 colonies of bees last spring, about the first of May. I removed the cap, covered with wire cloth, and moved them on a spring wagon. Box hives I invert, and cover the same way.

Mr. Simon said, I use the Peet cage for introducing queens. I sometimes coat the queen with honey and introduce at the top of the frames. I generally have good success, either way. I always feed the bees when I introduce a queen, if there is not a good flow of honey.

The question of our future meeting came up for discussion. It was suggested that we have a picnic dinner, bring our wives and children, and have a good social time, and that we

have a general display of bee-keepers' supplies.

Adjourned to the first Saturday of May, 1883, at the Center of Berlin.

Best Bees—Reply to Mr. Demaree.

JAMES HEDDON.

The discussion of the question of which are “the best bees,” has been before the general bee-keeping public for some time. They have, no doubt, heard about all they desire to hear on that subject, at least from Mr. Demaree and myself, who seem to be the chief disputants. My last article was an endeavor to sum up as clearly as possible, not only what I believed to be vital truths connected with the subject, but what I believed were generally accepted as facts.

I was incorrectly reported to have said, at our State Convention, that light Italians were more gentle than the dark ones. Like a drowning man catching at a straw, Mr. Demaree used this “phantom” with which to open controversy on a worn-out subject. That it is worn out with him, is evinced by the fact that his article on page 82, says nothing about it; the afterpart of it being, “how it market honey,” while the forepart consists of a series of assertions regarding my inability, etc. These points should be left with the readers to judge for themselves; should they not? This acting as chief disputant and judge, is again repeated by Mr. D. Is he afraid to leave it to the readers? Is he disheartened by the statement of Dr. Baker, in his article on page 74, 6th paragraph? Mr. Demaree must know that I am not the author of the term, “long leather-colored Italians.” He says it is an “egregious blunder” for me to confine the term long, to the darker Italians. I will try to show why it is not. I have never seen any Italians of the light hue as long as the average of the darker ones. I have always heard leading breeders, that I have met with, speak as though they never had. Never having seen, heard or read of such lengths and colors combined, as Mr. D. mentions in his second paragraph, where does the blunder come in? If Mr. D. has seen such, we are both consistent, and no one has blundered.

Mr. D. asks, “Is life a great tread wheel?” to which I reply, too much so with many of us. He infers that I am a “bread and butter writer.” Good. If I have written anything which has even helped to lessen the struggle for bread and butter, that is, to make the getting of it more simple and easy, be it ever so little, I shall be at any time proud to compare my record with his, as an apicultural writer. About his ability as a honey vender, I will not imitate him, but leave each reader to judge for himself. In the remainder and forepart of his article, he says, that I am not only a “blunderer,” but a “confuser,” that my articles “are replete with errors,” “marvelously superfi-

cial," "do not attempt to controvert a single important proposition, except in the way of unscientific bread and butter arguments," etc.—as though "science" (known facts) is something separate from bread and butter getting. If "science" has naught to do with our "dollar and cent" success in bee-keeping, let our future scientific articles be few and far between. The above assertions regarding myself, and disregarding the subject, reminds me of the following:

Por.—Why, man, what's the matter? Don't tear your hair.

Sir Hugh.—I have been beaten in discussion, overwhelmed and humiliated.

Por.—Why didn't you call your adversary a fool? Sir Hugh.—My God! I forgot it.

Dowagiac, Mich.

[Any controversy that descends to personalities is not only unwise, but is generally distasteful to the average reader. Mr. Demaree had the first article, and with this rejoinder of Mr. Heddon, we will, for the present, at least, dismiss the subject. Both disputants have "had their say," and anything more will be but a repetition, or drift to side issues and personal allusions.—ED.]

For the American Bee Journal.

Nebraska State Convention.

[Concluded, from page 84.]

The remainder of the time was devoted to discussions and informal proceedings.

Question: "Where, in the hive, do bees cluster most?" Mr. Turney said, his bees invariably clustered in that part of the hive nearest the entrance.

M. L. Trester thought they clustered at that point in the hive where the temperature, ventilation, honey, etc., came the nearest to meet their requirements, therefore, in different hives the cluster varied in its location.

The size of section boxes, was then discussed, and Dr. McAllister thought that we must supply the demand whatever size it may require—half-pounds or otherwise.

Mr. Corbett would use wooden separators, and $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ boxes.

Mr. Rouse said, that we could not afford to use the half-pound sections for the extra pay that was in them.

Dr. McAllister said, that the bees were apt to build their cells of an uneven length in any size of section, and Mr. Meyers concurred with him, although he has dispensed with separators.

M. L. Trester believed they preferred an even length in the brood nest, but outside of it they would run to both extremes of long and short cells.

The president said, they preferred a certain length, that he should return to the sections $1\frac{1}{2}$ inch wide. If he found that he had more sections on than the bees could occupy, he would exchange those inside for the outer ones.

Mr. Rouse: As yet I cannot get along without separators.

C. A. Speice asked, which was most profitable, comb or extracted honey?

O. Meyers believed it depended on the market; that he could get three times as much extracted as comb honey.

Mr. Speice was of the opinion that there was no trouble in marketing, if the people were only educated up to a point where they had confidence in the producer and dealer.

The president knew that some people liked the flavor of wax, spoke from experience; he also favored a trade mark on honey packages.

Dr. McAllister said, that very few people knew that wax was indigestible.

Several members thought that the glucose traffic was illegitimate, and ought to be crushed.

Mr. Trester believed that it was cruel to kick a dying man, and as the glucose business was at present in a very unhealthy condition, it would be humane to let it die in peace.

The question of a State trade mark for honey was discussed at length, without any very definite conclusions.

In regard to single and double-walled hives, Dr. McAllister said, the former are the hive.

T. L. Whitbeck had used chaff hives, but did not like them; he believed they were too warm, thought bees were thermometers, and the chaff hive would become so warm that they would fly out and be lost, in the cold weather; he puts his hives close to the ground, and makes a telescope for them, but did not think it paid; he thinks bees require a great deal of ventilation.

Mr. Rouse: A chaff hive, if properly made, is a ventilator of itself. The cost is no more than the cost of protection, in any other way. He has failed to keep bees too warm, out of doors. He said he took charge of the Omaha apiary in February or March, 1881, in the cold winter, and found that the bees had been put on to five or six frames, in chaff hives, with chaff cushion, and some hay thrown on top. There were about 2 feet of snow, and the hay had become full of melted ice, so that it had to be chopped away; the entrances had become entirely filled with ice, so that they had to be opened with a small chisel; the hives were close to the ground, and in spring they only lost 9 out of 107. In the winter, he found the top of the chaff cushion covered with frost, that looked like snow, but it was warm inside the cushion. Two inches of chaff is about right. In winter, he examined and found the bees lively, and the sides of the hive were dry. They consumed only 4 or 5 pounds of honey.

Dr. McAllister used to think that several auger holes were necessary for ventilation; now he thinks the crevices about the top of a hive sufficient; he believes that gluing is evidence against top ventilation.

Mr. Speice strongly believes in chaff hives, wants 2 inches under, 3 inches on the sides, 5 inches in front, and a 3-inch cushion on the top. He puts a kind of a hood over the front of his hives, so that the bees can take a promenade if they wish, when the weather is too cool to fly.

The president does not believe in late manipulation.

R. V. Muir wanted to know the relative cost of cellar and out-door wintering.

N. Pierson believes that drone eggs are often laid by workers while the queen is present in the hive, while Mr. Hawley was of the opinion that the queen lays all of the eggs, from the fact that as soon as she is removed laying ceases. Fertile workers are undeveloped females; they are detected by seeing several eggs in a cell, in irregular and improper positions.

The president said, that they will consume double the amount of honey out of doors than they will in the cellar. It is advisable to keep them in the cellar until there is honey to gather, if you can.

Mr. Fletcher asked if basswood will grow in any soil.

Mr. Speice: No, it will only thrive in a damp soil. I have some on high land that hardly grows at all. I have not mulched any.

Mr. Muir: I think they will thrive anywhere.

G. M. Hawley: I have some on second bottom, and they grow very fast.

Mr. Meyers stated that the Rocky Mountain bee plant would grow in Nebraska.

Mr. Corbett: I know that it has been growing west of Omaha for the last four or five years. It is also known as "Texas bee plant;" it has magenta or purple blossoms; the seeds grow in pods like mustard seed, only dark and rough.

How many bees can be kept profitably in one hive, was inquired and answered by the secretary; the number that can be kept in a hive, under favorable circumstances, without their desiring to swarm; but when they want to swarm, you might as well let them have their way, to a limited extent.

The president did not desire such large colonies, to get comb honey, as was considered necessary by most beekeepers.

What shall we do with lazy queens, was asked. The president said, pinch their heads. The secretary stimulates in various ways, such as strengthening, or exchanging combs, with adhering bees, with enthusiastic colonies, and finally pinches her head if all other means fail.

C. H. Rose had a lazy queen last year; but this year she is good.

Is "honey dew" good honey? was asked. The president said, that from aphides is certainly not.

G. W. Stark had seen honey dew on all kinds of leaves, but saw no aphides. This dew came in July, and was all consumed by bees.

Mr. Muir: We have a large yellow willow that the bees worked on for a week, then I noticed glistening sticky leaves; this was from the plant louse, and the honey was of fine flavor and good color.

The Convention having been in almost continuous session for two-and-a-half days, a committee on resolutions consisting of C. L. Speice, Jos. Baird and Miss Ada Hoyt was ap-

pointed, and during their absence a general visit was indulged in, all appearing to enjoy themselves, and seeming to regret that they would not be likely to have an opportunity to meet again until the second Thursday in January, 1884.

The committee reported the following resolutions which were adopted:

Resolved, That the thanks of the Association be, and are hereby tendered to the people of Wahoo for their kind hospitality so generously extended to the members of the Convention, and be it further

Resolved, That we hereby tender our thanks to the B. & M. and the U. P. railroads for the encouragement given to apiculture by reason of furnishing reduced rates of fare to our members.

Adjourned. M. J. TRESTER, Sec.

For the American Bee Journal.

Figuring up the Large Yields.

GREINER BROS.

On page 58 of the BEE JOURNAL for 1883, we find this: "I like the BEE JOURNAL, but I do not take much stock in those large yields published. I will give these parties \$500 in cash to instruct me how to obtain one-half that quantity, and pay all expenses besides. I suspect that it was not weighed on standard scales."

Our reply is simply this: If Mr. F. will guarantee or produce annually such honey seasons as we had in 1881, we will guarantee him the same large yields. It is only necessary for him to take the position of scholar and accept Mr. Doolittle's writings as instructor; this he can have without love or money, except \$2.00 yearly subscription for the BEE JOURNAL.

Perhaps Mr. Heddon, or, in fact, almost any experienced veteran of the fraternity could lead him to success; the reason we mentioned Mr. D. is because we happened to take him for our guide, and a good one it was, too, for we feel indebted to him for the 400 lbs. we took from one colony (spring count), a year ago. It is true, we used no standard scales to weight it, for it would be almost impossible, or, at least, a great loss of precious time to run to the scales with every section, and weigh, and record it, when we have all we can possibly do to take finished sections and replace empty ones, which is the case in a good honey flow. We use 2-lb. sections exclusively, and the only way of keeping account of yield we find practical, is, to record the number of sections taken from each hive, and this we do with pencil, on each cover.

When the season is past and the honey all handled and weighed, it is an easy matter to figure the average per colony, of the season, and if we wish to ascertain the yield of any particular one, all we have to do is to raise the cover and add the number of sections taken, which, multiplied by 2, will give a very correct report in pounds. To be sure, sections will vary some, according to the filling of the bordering cells, but what differ-

ence does it make in a report to call 99 sections 200 pounds, when, by actual weighing they might have overrun or fell short a pound or two, as long as it is the best we could do. The reason we give our yields in even pounds is, because it is easier to say 400 lbs. than 399 lbs. 14 $\frac{3}{4}$ oz., and, besides, the latter is just as liable to vary a trifle as the former, unless obtained by actual weighing, which, we think, no extensive bee-keeper can afford to do in the hurry of the season.

We do not blame Mr. F. in the least for doubting these statements, for we were troubled in the same way until the summer of 1881, when our own eyes witnessed what our reason had tried to disbelieve. It taught us the lesson to be very careful about doubting the veracity of our fellow men, especially when these doubts were publicly expressed.

On page 60 we find "A Candid Request," with an additional remark by the editor. As an explanation to these, we will give a short account of the way we obtained 400 lbs. from one colony, spring count.

The colony was divided in proper time and the queenless half at once supplied with a laying queen. Soon after, one of these divided colonies gave us a natural swarm, which was hived on a set of empty combs and the mother colony again supplied with a laying queen. The one that did not swarm, filled and finished 6 half stories, each containing 15 two-pound sections, and the seventh was all built out and nearly filled, with quite a number of sections finished, so that we estimated (not weighed) the contents to be equal to 8 or 10 finished sections. The whole yield of this one-half of the original colony being thus, 99 sections or 200 lbs., as given in our report. The other half, which cast a swarm, finished 3 half stories and about one-half of the fourth one, so that the yield of this one was figured at 52 $\frac{1}{2}$ sections or 105 lbs. The natural swarm was hived in our absence and could not be traced, so we took the average yield of our natural swarms as a report for this one, which was 41 sections, or 82 lbs.; they all worked pretty near alike and we were not far from a correct result by doing so. The sum of sections taken from these (now 3 colonies) footed up to 192 $\frac{1}{2}$ sections or 385 lbs. We used no foundation to obtain this amount except a starter of about 1 $\frac{1}{2}$ x 3 inches in each section.

When putting up the honey for market, our crates, of 20 sections, averaged from 41 to 42 lbs. net, on account of their being well filled and capped clear to the wood of the sections, and from this we figured 1 $\frac{1}{2}$ lbs. additional for every 20 sections, or 143 $\frac{3}{4}$ lbs. in all, making an aggregate of 399 $\frac{3}{4}$ lbs. from the original one colony, and this we called, in our report, 400 lbs.

Now, if there is anything wrong in our figuring the number of pounds, as stated, or, if the swarms were doubled to more than the capacity of one ordinary hive, by giving them all the section room they saw fit to use, then

we are at fault, and would be pleased to be corrected.

Our report for 1882 is very different to that of the year previous; whilst the latter was the best season we ever had, the former was the poorest. One apiary of 60 colonies gave about 40 lbs., and another, of the same number, about 34 lbs. per colony, and hardly any increase at that.

Mr. F. claims to be the first person who adopted wood separators in this country; we have used them since 1877 and recommended them years ago, through *Gleanings* and the BEE JOURNAL. Several others have also given their experience lately on the same subject, and their points of argument in favor of wood seems almost like a repetition of what we wrote at that time. We were opposed in argument by much better informed beekeepers than we claimed to be, and withdrew from the contest. Still, we continue to use them to this day, and have now no surplus arrangement without them; we can endorse all that Mr. Isham claimed in their behalf on page 54.

For the American Bee Journal.

Trying Ordeal for the Bees.

L. JAMES.

Bees that are on their summer stands, in this section, are passing through a severe ordeal this winter, and just now their endurance is being put to the test. After a long, cold spell, on the 2d inst. it moderated a trifle and began snowing, in the morning; later, turned to a light rain and a northwest wind sprung up in the afternoon, and freezing as fast as it fell, coating every object with which it came in contact. By midnight, the limbs of fruit and shade trees began giving way from the weight of accumulated ice, and the crashing and snapping from that time until 10 o'clock next morning, was terrible, and the damage to our trees is great.

I was unable to visit my apiary until to-day, it being a mile from town. The sun shone clear and bright, just as if nothing was wrong about here, and, I must say, that the sparkling and glittering of the icy diamonds in his clear, cold rays, as they swayed to and fro, was a splendid sight to behold, but when I walked out to the orchard where 39 colonies of my bees were, I thought the thing was entirely overdone, and I saw nothing beautiful in the prospect before me, for there they were, buried up in a wilderness of icy limbs and brush, glued fast at every point wherever they came in contact with any object—bee hive, cover or ground. While standing there and looking at the damaged fruit trees, and studying how to get to the almost inaccessible hives, I was very much impressed with the belief that when the thermometer stands at 95° in the shade, an apple orchard is a very good place for bees, but in such times as these it does not appear so. I was able to get at nearly all of them, and found the entrances, in nearly all.

completely closed with frozen snow, ice and dead bees; the covers frozen fast to the hives, limbs of the trees, and long icicles pendant from the covers and porticoes, all round them. I opened the entrances as well as I could, and, in most of them, the bees seemed lively and in force, coming out as soon as relieved. The honey boards being off and cushions or quilts being on the frames, saved them from being smothered. Three colonies, I think, are dead, and more probably, will be if such a state of things continue much longer. I have over 120 colonies in a cave that I do not feel much anxiety about, but could not get to see them as the outer door was frozen fast.

Atlanta, Ill., Feb. 5, 1883.

For the American Bee Journal.

"Why I am a Novice."

B. F. WOODCOCK.

I can recollect of no period of my boyhood when I did not long for a colony of bees. My aspirations ran no higher, at first, than one colony; but I wished for that more than any other earthly possession. My father was a lover of honey, but a despoiler of bees. The latter propensity predominating, he chose to buy his honey, much to my discomfiture.

When about 15 years of age, I concluded to have a colony of bees, at all hazards. A visit to the apiary of D. Z. Kagarice (a disciple of Langstroth, and a resident of Bedford, Co., Pa.), confirmed me in this resolution. I made a conditional contract, and went home highly elated with my prospects, while visions of an abundant supply of nature's choicest nectar, passed through my mind.

As my exchequer had never risen to half the amount necessary to purchase a colony of bees, I was obliged to make my wants known to my father, who positively declined furnishing any specie for that purpose. I then proposed to work out until I earned the sum required, but was refused the privilege. My ardor exceeding my judgment, I continued to importune him about the matter, until he, one day, gave me very distinctly to understand that he was running that *ranche*, and that while he did there would be no bees buzzing around his ears.

My air castle crumbled, the prospective bee yard vanished, and I threw up the sponge. Permit me to say (without intending the least reflection upon my father), that cold water of this kind has dampened the aspirations of many a boy, and turned him from a vocation for which he was naturally adapted, to one for which he had neither inclination or adaptation.

I have neglected to state that, at the age of 10 or 12, I was the possessor of a miniature apiary of bumble-bees. I secured the nuclei in the fields, early in the summer, and transferred them to box hives about 6x6 inches square and 5 high. I placed these on a broad board, elevated about a foot

from the ground, and put a good roof over them. I did not divide for increase, neither did they swarm. In the fall I used brimstone to secure their treasure, and was as happy over my pint cup full of honey as is Mr. Heddon over his thousands of pounds.

To atone in part for my "blasted hopes," I paid frequent visits to Mr. K. and his apiary, and would sit, for hours, an attentive listener to his plain practical exposition of the habits and instructive wisdom of the honey bee.

After attaining my majority I again applied for the privilege of starting an apiary on the old homestead, promising to buy the bees myself and share the surplus honey with the family, but my father could not be persuaded that he would not be a target for their javelins (as he terms them), and kindly refused.

Having selected a partner for life, who, by the way, is an apiarist of no mean pretensions, I, or rather we, came to the Hawkeye State, and in the fall of the same year (1876), purchased two colonies of black bees. Of my subsequent experience I shall have something to say in the future.

I am very much pleased with the *Weekly Journal*, and prefer it to a monthly.

Felix, Iowa, Jan. 7, 1883.

For the American Bee Journal.

Half-Pound Sections and Separators.

A. J. FISHER.

Mr. Heddon requests all to give their opinion on the half-pound sections. It is my opinion that they are too small to be profitable to the bee-keeper. It is true that some may demand them, but are they willing to pay the extra price above the one-pound sections to make them profitable to the bee-keeper? I say, no; considering the extra expense of construction and the less amount of honey obtained in them, my opinion is that the bee-keeper that put his honey up in half-pound sections will never compete with that one who uses sections from one to two pounds.

Those who are contemplating using the half-pound sections during the coming season should take the advice of F. C. Benedict, on page 8, who, I think, talks squarely on the half-pound sections. As for separators, I think I will have no use for them in the future.

I use a section box 1½ inches and 11-16 inches thick, and have eight and nine of them combined together, as one solid box, without separators, making a capacity of about 9 pounds. And I am one of those who claim that honey will be stored in a box of that style, where the bees can assemble in a large cluster and keep up the required heat for comb building, much faster than if each box was separated with a piece of tin or wood, besides the expense of construction, to use tin or wood.

Economy is the road to wealth. Those tin separators, with kinks in them, filled up with bee glue, are

dirty and sticky things to handle. In the above style of box I have no such dirt or traps to work with, and I expect to crate my honey too.

Am I right or wrong in regard to more honey being stored without, than with separators? What does Mr. Heddon say to this question? I predict that the time will come with "the knowing ones," that tin separators will be "things of the past." Can we not have, from the knowing ones, more discussion upon the question of how to get the most honey in a given time in the most marketable shape (not in half-pound sections), and benefit all concerned?

East Liverpool, O.

For the American Bee Journal.

A Report from Kansas.

HIRAM J. WARD.

After keeping bees 14 years I am going to try and make my first thorough report, at least as far as amount of surplus honey and marketing the same is concerned. The forepart of the year 1882 was very backward, being cold and wet, and as I am situated where there is no basswood, nor white clover, my bees were compelled to live on fruit and wild flowers, until alsike clover began to bloom. They gathered no perceivable surplus until the middle of June, and then for only a few days, and not enough to fill any sections. For about six weeks they only gathered enough to live upon, but I had a lot of old combs partly filled with honey from the bees that died in the winter of 1880-81, and I gave them to the bees, to stimulate breeding, hoping for a change in the weather, and sure enough, it came about the first days of August. On the 7th, I had a natural swarm, and others on the 8th, 9th and 10th.

I had given up all hope for the bees, and turned my attention to the farm, and marketing early apples (for I have a large orchard), but as soon as they began to swarm, I knew there was honey, and so on Aug. 8, I extracted my first honey from an eight-frame Langstroth hive, without top story, emptying a few combs only, to give the queen room, and put on the top story full of sections. From that time until frost, I had all I could do to take the honey and keep them from swarming.

This being my first year with Langstroth hives and sections, I had some trouble to get the sections evenly filled, for I have never used any separators yet. I have used three kinds of hives; the original American, the Quinby and the Langstroth, but I am putting all of my increase into Langstroth hives now, and shall change all from the American into them, by degrees.

I commenced in the spring with 17 colonies, and increased to 25 by natural swarming, and took 437 pounds of comb honey in sections, and 872 pounds of extracted, and have sold all of the comb at 22½ cts., and nearly all of the extracted at 14 cts., at home. Total, \$220.40; an average of \$12.961½

per colony, spring count; all done in just seven weeks. Besides, I have about 300 pounds in brood frames that I did not extract, for feeding next year. I have never fed a pound of anything but honey, and have been successful. I am seeding pastures of clover and other honey plants, so as to give my whole attention to bees and apples, but as soon as I get enough bees to keep me busy I will turn the apples over to somebody else.

Farmington, Kans., Feb. 5, 1883.

For the American Bee Journal.

Large Yields—A Review.

J. V. CALDWELL.

On page 60, present volume of the BEE JOURNAL, Mr. S. J. McKennie wishes bee men to be candid and let their readers know from how many colonies they obtained their large yields of honey, and also says it would be better to exaggerate less. Mr. F. H. Finch, on page 58, also wishes to pay some one a pile of gold to instruct him how to get one-half such crops.

Now, in all candor, gentlemen, would it not be better to acquaint yourselves with the facts in the matter, before intimating that some overstate the results?

Let us look at the matter a little. On page 59, Mr. McKennie says he began with 5 colonies and increased them to 17; he took 450 pounds of honey from them, and admits he lost 200 lbs. of honey as the result of queenlessness, and his bees were put away with 50 pounds to the hive. Now, suppose he had concentrated the honey-gathering powers of the bees in the original 5 colonies. Might not the result of his summer's business have stood something like this? Leaving out 5 colonies, we have 12 with 50 lbs., making 600 lbs.; with the 200 lbs., making 800 lbs. This, with the surplus he obtained, making 1,250 lbs. This, divided by 5 (the original number), would give him 250 lbs. to each one, spring count, which, at 18 cts. per lb., makes the nice sum of \$45 per colony. Which, Mr. McKennie would say, no doubt, looks like an exaggeration; but as a matter of fact, is not.

Now, for one short item of personal experience, and which I can prove beyond a doubt. Last season I had one colony, which, without any help, and although the forepart of the season was very cold and wet, (they were not fed an ounce of honey or sugar), gave me 235 well-filled one-pound sections, and 10 lbs. of extracted honey. They did not attempt to swarm, and they did more than this. I had my bees sitting on brickbats, close to the ground, and, although they did not cluster out, a lot of them went under the hive and built comb enough to store several pounds of honey, where I could not see them. These bees were what I call Italian-hybrids, a pure queen probably mated with a hybrid drone.

I entirely agree with Mr. Heddon, on page 53, and although I would prefer the pure Italian if it had all the good qualities we desire, yet, I shall certainly breed from my best honey-

queens, let them be yellow, black or mixed. During my early days in the business, my great ambition was to get the yellowest and handsomest Italians. Now, the same ambition leads me to obtain the greatest amount of honey from the least number of colonies.

Who will rear queens that will pile up the honey, or rather, infuse the energy into their progeny, to roll in the honey without frittering their time away in swarming and idling? I should be glad to pay \$5 each for such queens.

I have several queens that I could not be induced to part with at double that figure. In saying this I have no "axe to grind," as I do not rear any for sale, and do not expect to. We who are putting our time and talent in apian pursuits must look at these things from a strictly business point of view.

Cambridge, Ill., Jan. 24, 1883.

For the American Bee Journal.

Honey and Bee Show in Nebraska.

T. L. VON DORN.

EDITOR BEE JOURNAL:—Please let me call attention to the Premium List of the Nebraska State Board of Agriculture: Class 6 $\frac{1}{2}$. Best colony of bees, 1st premium, \$25; 2nd, \$10; 3rd, \$5. Comb honey, 1st, \$25; 2nd, \$10; extracted, \$5; 2nd, \$3. Best display of honey, in marketable shape, \$10 and \$5; apian implements, \$10 and \$5; foundation, full to partly drawn, \$5 and \$2. Open to the world, except on honey, which is limited to Nebraska.

Now, I think we have secured a fine premium list, and we are anxious that our neighbors compete at least for the premiums on best bees. The test is, net gain in stores, for two weeks, and will commence the latter part of August and end during our State Fair. The superintendent is a practical apiarist, and a man who enjoys the confidence of every one who knows him, and every precaution is taken to ensure accurate and just results.

I have taken the premium on bees for two consecutive years, and I propose to do so again, if I can; but if any one else can show us better stock or management, he will find a hearty welcome to the prize, and a good market for some stock. The conditions are that all the bees in the colony shall be the progeny of the queen and colony on exhibition. That they shall also show the usual docility or amiability of pure Italians.

I voice the feelings of the Nebraska bee-keepers, when I extend a cordial invitation to all those who have choice stock to come and get the \$25, if they can. I shall be glad to give any further information desired.

Omaha, Neb., Feb. 5, 1883.

[We congratulate the bee-keepers of Nebraska on their success in obtaining such an excellent Premium List for the Bee and Honey Show, and sincerely hope it will have the desired effect.—ED.]

SELECTIONS FROM OUR LETTER BOX

Statistics for New Jersey.

After correspondence with Dr. Miller, I find that I can best carry out the auxiliary purposes of our Association, by requesting the fraternity in New Jersey to forward their reports at once to Dr. C. C. Miller, Marengo, Ill. Give facts on a postal. Do it now.

C. W. RUE,

Bees and Grapes.

For ten years, or more, I have had very fine Virginia grapes in front of and very near my apiary, and, to my great surprise and deep regret, the bees do not "injure" my grapes. I wish I could get them to "go for" the grapes, peaches and all other fruits. Last summer I had as fine grapes as I ever saw, but the bees sucked none but those which were "injured" by geese, chickens, wasps, etc. The story about the "Honey in the Rocks," belongs to California instead of Virginia. E. C. JORDAN.

Stephenson's Depot, Va.

My Wintering Troubles.

Last January I purchased 10 acres of land at Hagerstown, Md., intending to put up a building early in the spring, and be located there by harvest. I commenced in April, but the weather being so very unfavorable for building and bees, being disappointed in labor, etc., I found it would be impossible to go on with my building, and fill my orders; so I postponed the building until after harvest. Aug. 1, I commenced building again and my time was so much taken up during the fall that I thought I had no time to look after my bees, and I thought they were all pretty well supplied with stores, except those at Hagerstown, so I congratulated myself that my bees were strong in number, with plenty of stores, and did not need special attention, and out door wintering might do pretty well after all. Cold weather set in about Nov. 20. I still expected some warm weather, but it did not come and about the middle of December I put the weakest of those at Hagerstown in the cellar, and thought the rest of them might go through out of doors, but by Jan. 10 I found it would be a failure, so I moved them into the cellar, and they are doing well. I have spent the most of my time this winter at Hagerstown; I am at Double Pipe Creek, to-day, making arrangements to move next week, and thought I had better look after my bees, and, to my disappointment, find them in a very bad condition. Ten colonies had already perished; a few may have starved for want of honey near the cluster, but most of them had the dysentery. My bees at this place have consumed an unusual amount of honey already, and are generally bloated, and if it does not get warmer soon, I fear the loss will be heavy;

there is an unusual amount of dead bees in the hives. As the weather is too cold to disturb them, out of doors, I did nothing more than to put a well-filled comb of honey, having a passage cut through it, over the cluster, which will be sufficient for them until the middle of March, if dysentery does not kill them. I shall move part of them to the cellar and give them plenty of upward ventilation, and experiment with them and report later. I cannot say how my bees are wintering in Virginia and W. Virginia, as I have not seen them since the fall; then they had plenty of stores. We have not had extremely cold weather this winter, but it has been continuous for over 2 months, and damp, with no chance for a flight. S. VALENTINE.

Hagerstown, Md.

How the Bees are Doing.

This is another very severe winter. The weather has been very cold ever since Dec. 1. Old bee men think we will have another grand disaster, like the season of 1880-81. However, I hope they are mistaken. My bees had been confined since Dec. 1 until Jan. 27, when a portion of the bees had a flight. Those in two-story hives came out the most. When I say two-story hives I mean 2 hives, one on the top of another, with both entrances open. They seemed to be dry and bright. Those in one-story hives did not come out as much, although similarly located. Very few dead bees were under the clusters of the two-story hives, but considerable more in the single ones. The snow is over a foot deep; the thermometer, in the shade, shows 2° below freezing point. Comparatively few bees remained on the snow, considering the chilly air. The bees are packed in leaves, on the back and between, and the front open to the sunny side. The bees spotted the snow some, but not much.

H. S. HACKMAN.

Pern, Ill., Jan. 31, 1883.

Sundry Questions.

My 35 colonies are all packed on their summer stands in straw, chaff, leaves and cobs, as an experiment. They had a good cleansing flight on Dec. 24 and Jan. 28. They seem to be strong and healthy, so far. The index for 1882, is a great convenience. I have been looking over and reviewing some of the articles written last year. I intend to try Prof. Cook's plan of preventing increase, on page 474, July 26, 1882, and if it works well with my bees it will be worth more to me than the price of the BEE JOURNAL for a year. Mr. Heddon's honey board is new to me. When the sections are all on and full of honey, will not those $\frac{3}{8}$ inch slats sag in the center with the weight, or how is it prevented? Will Mr. Heddon tell us? Do you think the one-piece dove-tailed sections as good as nailed ones? Do you know anything about Lowmaster's drone trap, referred to on page 313 of the BEE JOURNAL for May 17, 1882? I want one of some kind. Does not Prof. Cook and others teach that the brood combs must be

3 inches from centre to centre? That is what I understand; if so, how can you get ten frames in a hive of 14 $\frac{1}{2}$ inches, as the Langstroth hive is described on page 55, Jan. 24, 1883, by M. M. Baldrige? I have been taught and practising with a hive 15 inches wide for ten frames, and 12 inches for eight frames. I never handled the movable frame hive much, and I want to be sure I am right; "then go ahead." D. S. KALLEY.

Mansfield, Ind.

[We believe the one-piece sections are as good as any, and are superseding all other kinds. We know nothing more of the drone trap than is mentioned by Mr. Lowmaster.

You are mistaken about the distance between brood frames. Prof. Cook, as well as all others, state that the distance should be about 1 $\frac{1}{2}$ inches from centre to centre.—ED.]

Hard Winter—Bees Dying.

Bees are beginning to die, here. A good many colonies, with chaff and similar protection, are dead. I have about 100 colonies in a well-ventilated bee-cellar, that begin to show symptoms of dysentery. The cellar has been of uniform temperature, about 35°, with all other conditions favorable, but present prospects of successful wintering are not promising.

LEONIDAS HUBBARD.

Waldron, Mich., Feb. 12, 1883.

Last Season's Work.

Last spring we had 14 colonies; increased, by the middle of July, by natural swarming, dividing and nuclei, to 24, and there we set our stakes. But bees, like many others, are whimsical. On the last of July they commenced swarming. Nearly every pleasant day out came a swarm, and when threshing; while I, with the assistance of a young girl, was getting dinner for 19 men, one day, two swarms came out; the next three, between 10 and 12 o'clock (bee-keeping and farming makes lively work; no time for blues, dyspepsia, and other luxuries of that kind). Well, I dropped all, to help hive or return them. One swarm, of our best Italians, the largest I ever saw, had come out, two days previous, and had been returned. The third time they clustered on an apple tree, near by. We hived them under it, and when I saw them going in nicely I skipped to that dinner. I never forget the old adage, "The way to a man's heart is through his stomach." I think it was my nice bread and butter that made such a big hole in my husband's heart (and I really believe honey has a tendency to make it larger every day). In the hurry, instead of putting on the cover, the "gude mon" laid a board on top of the hive. Well, the swarm left, and the question is, was it for want of ventilation, or had its conduct of the two previous days something to do with it. We should learn from failures. They kept up their swarming till Sept. 1. Some we hived, returned

some, and 8, to our knowledge, absconded. On Sept. 1, 2 came out; the first we hived; it filled the body, and gave 20 lbs. in sections; the others we returned; hives were exhausted, so they stand 39, a very unromantic number. While extracting, during the middle of September, we found 5 colonies without queens. We imported 3 Italians, and introduced them safely. The others we gave larvae, and, on Oct. 5, they had queens. They are all on their summer stands yet, with chaff cushions and quilts over them. They were not fixed for winter when the blizzard came, and I am fearful. Does anybody ever get quite ready for winter? A word about that delinquent nuclei. They reared a queen about Sept. 1, and filled the body of the hive; we got about 1,000 lbs. of honey. Our best colony of the three, that did not swarm themselves to death, gave 125 lbs. of comb honey. Last year, comb and extracted honey sold readily for 20 cts. There is so much fruit here, this year, that honey is a drug. Egypt might be called, this year, if not the granary, the fruitery of the East. Thousands of barrels of apples have been hauled by our house one mile to the depot. There are two orchards in our vicinity of 150 and 160 acres respectively. There were hundreds of bushels of black or rather dew berries, picked from those orchards and shipped to Cincinnati and other points along the O. & M. road. We have sold 200 lbs. of honey at 20 cts., and 100 lbs. shipped away at little less. Many producing honey in the old way, bring it to town and sell at 12 and 13 cts. Mrs. C. J. ALLISON.

Noble, Ill.

Cellars and Summer Stands.

Time with his sickle is mowing the days and hours. Seasons come and go; days and months, like the seasons, succeed each other. Summer, with all the joyous anticipations that could be produced by the warm and genial rays of the sun, and change of the season, has given place to autumn, and this to cold bleak winter. We are all anxiously waiting for spring-time to come, hoping for the best results with our bees. The bees I put in the cellar seem to be doing finely; the thermometer registers from 40° to 44°; they remain so quiet you can hardly hear a hum; most of my bees are packed on their summer stands in sawdust, as recommended by Mr. Heddon, and all seem to be doing well, except one colony, which seems to be afflicted with the dysentery. On Jan. 7, when the mercury registered 20°, the bees from this colony flew out and stained the snow badly, and many died. I am not able to attribute the cause of this colony being affected, while the rest seem to be doing well packed in the same way. Perhaps it is owing to their long confinement, as they have not been able to fly out since Nov. 20. I am very much pleased with the Weekly BEE JOURNAL, its value has greatly increased, and it is now indispensable.

Disco, Mich.

E. W. WALES.

Queen-Rearing in Small Nuclei, etc.

Allow me to ask a few questions through the BEE JOURNAL, which may benefit others as well as myself. First, I have been binding the JOURNALS and other valuable papers myself with glue, which is not good. Will you or some of the readers of your BEE JOURNAL give a receipt that book-binders use to paste the book cover to the book, so that it is durable.

2. On page 741 of Vol. 18, BEE JOURNAL, Mr. G. M. Doolittle, says: "After using it a few years I ascertained that a winter that was favorable for outdoor wintering was not as favorable for cellar wintering, and *vice versa*, thus proving that the plan of mixed wintering was a good one. Again, if any one could tell just what the winter would be beforehand, I would place my bees in the cellar for a cold winter, and leave them out during a mild one." Will G. M. Doolittle tell us through the BEE JOURNAL what the thermometer will record for a mild winter, and what for a cold winter; as I notice in the BEE JOURNAL that there is from 6 to 8 degrees difference in the temperature between Mr. D.'s and here. The mercury was down to 6° below zero in the fourth week of January; for only two days.

3. On page 280 of Vol. 16, BEE JOURNAL, "No one ever found fault with Quinby's queens, reared in boxes, containing 3 or 4 frames, 5x6 inches square. Is the rearing of queens in Quinby's method a safe and sure way to rear queens?"

JOSEPH M. WISMER.

Jordan Station, Ont.

[1. Book-binders use glue, but of much thinner consistency than that used by carpenters.

2. Mr. Doolittle is invited to reply to this.

3. No; the writer of that article distinctly states that these small nuclei were abandoned on "account of the liability of the bees to abscond, and the amount of attention required to keep them in fitness." You should have read the whole paragraph.—ED.]

500 Pounds from One Colony.

I commenced the season, about June 1, with 30 colonies, almost destitute of honey; increased to 65, in fine condition for winter, and obtained 4,538 lbs. of honey (807 of comb, in 2-lb. boxes, and 3,731 of extracted); I have about 300 lbs. besides, stored away, and not counted in my report. My best yield from one colony was 486 lbs. of extracted. I think that I took enough comb honey from it, not included in count, to make over 500 lbs. I fed about 3 lbs. of sugar in spring, but the bees received no other help; got no increase. Time of extracting: July 5, 42 lbs.; 15, 26 lbs.; 21, 68 lbs.; 28, 75 lbs.; Aug. 24, 90 lbs.; Sept. 7, 105 lbs.; 19 and 20, 80 lbs. Had I used three instead of two stories for surplus, I think I could have obtained at least 600 lbs. I was crowded too much with other work to attend to it, as I should, or I could have made a much better

showing for my bees. The cell producing this queen was obtained from a strong colony of bees which started only this one cell, during basswood harvest. Could I have another such a season (which was very poor at the commencement), and such a queen, I think that I could get 800 or 1,000 lbs. of honey. If cold weather kills bees (as I think it often does), we may look for considerable mortality among our pets next spring. The lowest temperature noticed here, so far, is 35° below zero; it was 29° below on Feb. 2, at sun rising; and away below, every morning since. My bees all answered to the roll call a few days ago, and seemed in good condition. I have them in a good dry cellar, with about 5 inches of leaves packed above most of them. W. C. NUTT.

Otley, Iowa, Feb. 7, 1883.

A Smart Three-Year Old.

"It's a daisy; it's a daisy." Such were my exclamations on taking the wrapper off my BEE JOURNAL, dated Jan. 31. My wife wanted to know what was a daisy, and after drawing her attention to the new coat the BEE JOURNAL had assumed, she said it was "a pink." My little boy, 3 years of age, came running up and asked me what was a daisy, and after showing him the BEE JOURNAL, said it was "real nice." By-the-by, you are not acquainted with my little son; well, when he was 2 years and 8 months old he could find a queen when caged. I claim he is the youngest bee-man known. He asks after his JOURNAL weekly, and I have to read to him. I think now you have a JOURNAL to suit the most fastidious. I, therefore, move a vote of thanks to you for the improvement.

S. G. HOLLEY.

New Hamburg, Ont., Feb. 1, 1883.

[We are glad that now ALL are pleased with the JOURNAL cover. But that "boy" is the brightest juvenile specimen yet heard of, and will "make his mark," as the years roll along. We were hardly prepared for "the news," that we were preparing reading matter to interest one so young as "under 3 years of age," as well as many who have seen over 80 summers. Give the little "chubby" a kiss from the editor.—ED.]

Bees in Kentucky all Right.

Bees are wintering very well here. The coldest weather we have had since the first week in December, was 6° above zero, and the warmest was 64° above zero. J. T. WILSON.

Mortonsville, Ky., Feb. 10, 1883.

Bees had a Flight.

Tuesday, Jan. 30, was clear and warm for the season, and my bees had a pretty good flight, and they needed it, for they have been shut in since about Thanksgiving day. Two light colonies, that I did not unite, are dead; the other 24 are in good condition, at present. I removed the

caps from the hives, to let the sun shine in, to dry out the dampness as much as possible, and the bees are now in pretty good condition for another very cold snap. The weather here has not been so very cold, but steady, with no thaws until this week; there is not a great quantity of snow, but we have had some very good sleighing. I call it one of the most healthy winters, thus far, for a long time, and hope it will prove so for the bees. R. DOWNS.

Naugatuck, Conn., Feb. 2, 1883.

Perfectly Satisfied.

I shall be perfectly satisfied in whatever way the editor "makes up" the BEE JOURNAL. I bind my own JOURNALS, and have just finished the volume of 1882. It is a nice work, and I would not sell it for \$10.00, if I could not get another.

WM. BOLLING.

Dunkirk, N. Y., Jan. 26, 1883.

Honey Used by Bakers.

Have you noticed the fact that the bakers are using large quantities of extracted honey, in their business, lately? It is news to me. I see our bakery here has been buying largely from Mr. Muth, of Cincinnati.

G. B. LEWIS.

Watertown, Wis., Feb. 13, 1883.

[Yes; they use it for cakes and pastry, of the best quality.—ED.]

Feeding Bees in Winter.

In an article in the BEE JOURNAL, the writer explains the way he feeds his bees in winter. I would like to know whether it is advisable to feed that kind of food in winter or not. I was afraid my bees would not winter very well, so when we had a thaw, the other day, I opened them and put under the sheet on the frames a cake of candy, made of the best white sugar, and which I think, with the honey they have in the comb, will last them until spring. I would like to know which is the best food for winter, syrup or candy? When I opened them they appeared to be in first-class condition, although I never saw them flying since the first cold snap in the fall. I winter them in the Jones hive, with inside packing.

WM. H. WESTON.

London, Ont., Feb. 1, 1883.

[We prefer the candy.—ED.]

Motto—"Push and Progression."

I am highly pleased with the change in the "make-up" of the BEE JOURNAL. Mr. Newman, you certainly deserve great credit, and the gratitude of your patrons, for your successful endeavors to bring the BEE JOURNAL up to the very highest point of excellence. *Push and Progression* seem to be your motto. May long life and great prosperity be your reward. Many of the communications are each worth the cost of a year's subscription for the BEE JOURNAL.

REUBEN HAVENS.

Onarga, Ill., Feb. 2, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., February 13, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. here.
BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, on arrival; dark and off colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extract brings 7c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival.
BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@c. to 14c. Extracted, 8c. to 10c., according to color.

BEESWAX—32@33c. per lb. for good.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is extremely dull. For comb of ordinary quality is almost impossible to find buyers. Good comb, of sage blossom, is offering at 13c.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@c. to 9@c.; dark and candied, 5@7@c.

BEESWAX—We quote 25@28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16c., strained, at 8@c. to 7@c., extracted at 7@c. to 8@c.—lots in small packages, more.

BEESWAX—Steady at 28@29c. for prime.
W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 16@20c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 9@10c. in bbls. and 11@13c. in cans.
BEESWAX—Scarce, 28@30c.

A. C. KENDAL, 115 Ontario Street.

NEW YORK.

HONEY—Choice to fancy white clover honey continues scarce and firm, but buckwheat and extracted honey slow and irregular.

We quote: White clover, first quality, 1 lb. boxes, 24@25c.; for to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c.

BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly.

Western pure, 30@32c.; southern, pure, 31@33c.
D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 3 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Convention Notices.

It seems as if we were getting behind in this part of Iowa, by not having a convention. On consultation with a few bee-keepers, it was agreed to call a meeting on Feb. 24, at 2 o'clock, p. m., at Columbus Junction, Iowa, to consider the practicability of organizing a Bee-Keepers' Society in Louisa county. D. RAWHOUSER.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.
G. W. DEMAREE, Sec.
Christiansburg, Ky.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.
WM. R. HOWARD, Sec.
Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nells's Corners on Saturday, March 31, 1883, at 11 a. m.
H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.
S. W. SALISBURY, Sec.

A bee-keeper from Sweden has just arrived in Chicago with a letter of introduction from Mr. Stalhammar, editor of the Swedish bee paper. He endorses him very strongly, and wants us to find him a place to care for bees. If any of our bee-keepers want such a hand, it will be appreciated if they will write to us. He speaks but a few words of English, but is a very healthy-looking man.

Articles for publication must be written on a separate piece of paper from items of business.

HELP WANTED!!!

An apprentice, or a partner, to join me in raising Bees and Honey on an extensive scale. The right person can, at the start, have a half interest in 150 or 300 colonies, depending on qualifications. For details, apply by letter or otherwise, to
M. M. BALDRIDGE, St. Charles, Ill.

1883. YOU GET VALUE RECEIVED! 1883.

QUEENS, BEES AND SUPPLIES

If you want EARLY QUEENS from the best improved genuine stock for business; or if you want imported Italian Queens or bees, in full colonies or nuclei, with tested or untested queens; if you want Danham or Vandervort comb foundation, made from pure beeswax; or if you want hives or apiarian supplies of any kind, send for my new catalogue. It tells you about introducing queens, new "Races of Bees," etc. Cash paid for clean beeswax. Address,

J. P. H. BROWN,
Augusta, Georgia.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

VOL. XIX.

CHICAGO, ILL., FEBRUARY 28, 1883.

No. 9.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Hives for Observation.

It is our aim to make honey a staple product. To this end we have endeavored to popularize the consumption of honey by the masses, as well as to raise the standard of production, by applying correct principles and progressive art to the management of the apiary.

Public manipulations with bees and magnificent honey exhibits are the most attractive features of State, County and District Fairs. There are many good reasons for introducing such, but the chief one, perhaps, is that those who produce honey for the market may be induced to present it in the most marketable shape; for the new methods and new ideas of practical management must take the place of the old and undesirable ones.

At the American Institute Fair, in New York, in 1877, Dr. Worrall exhibited a colony of bees in his hive,

DR. WORRALL'S OBSERVATION HIVE.

the brood chamber of which is shown in the engraving. It has glass sides all around, and it was a great attraction. Prof. Hasbrouck, Mr. Locke

and others, also exhibited bees in observation hives.

Bees and honey are already the great attraction at such Fairs as have given prominence to this industry—and this will become more apparent each successive year. Michigan, Nebraska, Missouri, and some other States, have tried a small Bee and Honey Show, and the results have been so satisfactory, that they are now intending to have them on a much larger scale.

When in Great Britain, during the summer of 1879, we found that the most attractive features of the Fairs were the public manipulations with bees, and the very large exhibition of honey of captivating beauty. For exhibiting bees, observation hives were used—those having glass sides, through which the bees may be seen at work—the hives being inside the exhibition building, with a tube covering the entrance, and running through the side of the building, giving free passage, in and out, for the bees. Sometimes, a glass box inclosing each frame, arranged like leaves of a book, with a common entrance to all of them, from the tube running through the side of the building, is made to exhibit bees. This gives an opportunity for thorough examination of the whole colony.

Prof. Cook has one of the latter kind in his study, and, by request, he has sent us a drawing of it, from which we have made the illustration, so that our readers will obtain a good idea from it and the accompanying description given by the Professor:

OBSERVING HIVES.

Of course, every live bee-keeper will possess and read one or more of the books that treat of bees and their management. These place the whole subject before him, and, if well indexed, enable him to study any particular phase of the subject at will. He will, also, if wise, take and read one or more of our excellent periodicals. These keep him versed in the progressive steps in his art, and the

various discoveries and improvements can be appropriated as soon as made.

There is still another method to gain knowledge, which though, perhaps, not so full of practical aid as the above, will greatly benefit, even on the practical side of our business; but, more than this, it will enable us to confirm what we learn from the books, and will do more than anything else to exalt our appreciation of the wondrous habits and instincts of the little insects with which we have to do. It will do much to make our life work as full of wonder and admiration as it is of pleasure and profit. I refer to the possession of an "Observing Hive;" so that, with each leisure hour, we may look into the very life habits of our pets. Such observation, in any field of natural history, always excites interest, imparts instruction and ennobles the observer.

Few experiences in my life have yielded more real pleasure and valuable instruction, than the hours spent in watching the strangely interesting labors of the bees, as studied in my library, by use of the small "observing hive," here illustrated.

PROF. A. J. COOK'S OBSERVATION HIVE.

I do not think we need any complex arrangement. A simple, uni-frame hive, with glass sides, which may be darkened by doors, is cheap, easily made, and will enable us to watch any operations carried on in the hive. I have even had bees in such a hive prepare to swarm. Of course, such limited quarters will not permit much increase, and so, when the brood commences to hatch out, the bees must be shaken from the frame, and it replaced with a frame of empty comb, or, better still, a frame of comb foundation. We then can watch the bees as they transform the foundation into

a sheet of beautiful comb. If the bees are not gathering at the time of this transfer, we must either feed them, or give them a comb containing some honey. We may now watch, not only the wondrous fashioning of the comb, but the laying of eggs, the packing of pollen, the finding of the larval bees, and the many other wonderful manipulations, to be witnessed in the "Observing Hive."

My hive, which is correctly represented in the engraving, is neatly made of black walnut, and forms, of itself, quite a pretty ornament in my study; while, with its wondrous contents, it forms an attraction which can hardly be surpassed. It will pay every apiarist to keep such a uniframe hive, for his own edification, the instruction of his children, and the entertainment of his friends.

Bees' Tongue Register.—We have received, from Mr. John H. Martin, one of his improved Bees' Tongue Registers. We notice that he has reconstructed and simplified it during the past year. As it registers by hundredths of an inch, it is a very useful article by which to measure the length of the tongue of bees, so as to determine those best fitted for collecting the nectar from red clover or other honey-producing plants which have a deep secreting cell. This is a step in the direction of "breeding the best bees," and we welcome Mr. Martin's invention as very useful and eminently progressive.

A beginner, J. L. H., fed the bees sugar syrup while they were out for a flight on Feb. 16, and says that they had a fight, some being killed by those of the same colony, and then asks: "Why is this?" Feeding the bees in the open air close to the hives, is always dangerous, and might have caused "robbing" to such an extent as to have given the beginner a "very dear lesson." He has two colonies each of black bees and Italians, and adds, "the Italians did not come out much." The angered bees were blacks (perhaps, hybrids), and, no wonder that they were on the rampage. They had feasted on the syrup, become angry because there was no more, and then fought over it.

The Baroness Burdette-Contts, who is not only the richest lady in the world, but the most liberal one, and who is also the President of the British Bee-Keepers' Association, gave a New Years' dinner to eight hundred of her tenants, and afterwards personally presented a gift to each one of her guests.

Average Intelligence About Bees.

Mr. H. R. Boardman, E. Townsend, O., sends us the following from *Good Words*, which is now "going the rounds of the local press."

Honey is, as a rule, very sweet and fragrant, but it is sometimes injurious to human beings. Here I may mention that no bee can suck honey out of flowers, as is popularly supposed. She licks it out with her tongue, the end of which is covered with hairs, so as to convert it into a brush, scrapes it between the jaws, and so passes it into the crop where it is changed into honey. What property may be in the crop which converts flower juice into honey, we do not at present know. To all appearance, the crop is nothing but a bag of exceedingly-fine membrane, and yet, after remaining for a little time in the crop, the flower juice undergoes a change of consistence, flavor and scent, and whether the insect is a wild or domestic bee, the change is identical throughout.

Mr. Boardman very aptly remarks that this demonstrates "how rapidly we are advancing in the knowledge of bee-culture, especially as promulgated by the average newspaper. It is too good to be lost. If knowledge were bliss, 'twere folly to be wise."

Honey Wine.—The Clarke Co., Va., *Courier* has the following:

Mr. J. Luther Bowers, a bee-keeper of this county, has presented us with a bottle of honey wine, the preparation of which was very simple, the only ingredients being honey and water. It was very palatable. From 51 colonies of bees he realized, last year, 1,250 lbs. of choice comb honey, 1,200 lbs. of which he sold for \$240. One colony furnished the enormous yield of 153 lbs., which, at the price he received for his honey (20 cents per lb.), brought \$31.60, or nearly as much as two acres of wheat. The value of such a colony reaches beyond \$100, and shows what energy and improved methods will accomplish. Mr. Bowers prefers to use the 1-lb. sections, as honey in that form commands a better price and sells more readily.

Letters and communications have accumulated so much that we give up the space this week to an extra quantity. Several long reports of conventions are waiting, but we give the communications a chance this week, before they get too stale.

We have received a copy of "The Simmins Method of Direct Introduction," a pamphlet of 28 pages, on introducing queens, detailing his methods and management, and may be had of Samuel Simmins, Rottingdean, Brighton, England, for 15 cents.

Answering Questions.—Mr. Heddon, Dowagiac, Mich., writes as follows:

I desire, and expect to be able to answer all questions pertaining to business transactions; that I must do as a duty, and I would not like to have it otherwise understood. But I have a host of long, pastime letters, mixed all through with questions regarding bee-culture, but I cannot possibly answer them all, and do the other work allotted to me. I will answer all questions sent direct to me, or to the bee-papers, on separate sheets, with spaces left for answers. JAMES HEDDON.

Questions for Mr. Heddon to answer, may be sent to us, or to him direct, and they will be promptly answered in the BEE JOURNAL.

New Catalogues and Price Lists.

We have received the following new Catalogues and Price Lists of Bees, Queens or Apiarian Supplies:

Dr. J. P. H. Brown, Augusta, Ga.
Naramore & Wood, N. Lansing, Mich.
Richardson Bros., Port Colborne, Ont.
Edward B. Beebe, Oneida, N. Y.
Wm. W. Cary & Son, Colerain, Mass.
W. P. Henderson, Murfreesboro, Tenn.
Wm. Ballantine & Son, Sago, Ont.
J. D. Goodrich, East Hardwick, Vt.
E. T. Lewis & Co., East Toledo, O.

SEED AND PLANT CATALOGUES.

Wm. Rennie, Toronto, Ont.
J. A. Everitt, Watontown, Pa.
F. E. Fassett & Bro., Ashtabula, O.
Chas. A. Green, Rochester, N. Y.
I. F. Tillinghast, LaPlume, Pa.
Also, Crawford's Strawberry Culture, Cuyahoga Falls, Ohio.

Several correspondents ask if it is essential to write only on one side of the sheet of paper when preparing an article for the JOURNAL. For us, it is just as well to write both sides, and saves postage in sending it.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1883, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

CORRESPONDENCE

For the American Bee Journal.

How Shall We Report?

G. M. DOOLITTLE.

On page 58, Mr. F. H. Finch takes exception to "those large yields published," and thinks they were "not weighed on standard scales." Also, on page 60, S. J. McKennie says, "I have the highest respect for intelligent and scientific statements, but no relish for exaggerated statements," and by the editorial note at the close of Mr. K.'s remarks, I see that you, Mr. Editor, are not just clear as to how a report should be made out. I once reported 566 lbs. in one season from 1 colony of bees, hence, I would be classed by Mr. K. as one of those "who exaggerate," and by you, Mr. Editor, as being one of those whose "statements are unfair, and mislead the unsophisticated." As I have never intended to be "unfair" or "mislead," perhaps it were well to look into the matter regarding how a report should be made out.

I had supposed it fair to give a report based upon the "spring count" of colonies in a yard, dividing the total production of honey during the season, by the total number of colonies in the spring, and qualifying by saying they increased to such a number. However, I now see that Mr. K. does not consider this as fair. But, supposing they do not increase at all, as was the case with Mr. Carroll's colony that gave the 800 lbs., would it then be fair to report 800 lbs. from one colony. The editor says not; for, in his case, he used "3 or 4 ordinary hives by extra stories one over another," thereby making his report "unfair and misleading."

But, again, supposing they did not increase at all, and were kept in a single story hive, as was the case with the colony which gave me the 566 lbs. Would it then be unfair to report that amount as the production of one colony? Although I listen intently, I hear no one say "unfair." Well, if the same number of bees, all the production of one queen, make the same number of pounds in 2 or 3 ordinary hives, by extra stories being placed one over the other, I cannot see why it should be more unfair than the other.

Again, if the bees swarm and are bived in a separate hive, and none of the young or second queen's bees are old enough to labor in the field, I do not see how it should be unfair to report the product of the two the same as if they had remained in one hive. The reason why these "big reports," as they are called, are considered "exaggerated," is that those calling them such, think as does Mr. K., that 20,000 to 25,000 bees constitute a colony. If we make 20,000 bees a standard from which to report, as does Mr. K., probably Mr. Finch will have no need of

offering his \$500 for some one to instruct him how to have his bees make one-half as much as some report, for his 20,000 bees will secure nearly or quite as much as will 20,000 of Mr. Carroll's.

In the spring of 1877, I selected an ordinary colony of bees, and set it apart for extracted honey. This colony was no better than one-third of my yard would average, and was not helped in the least from any other colony. I built them up as fast as possible, by the means I usually employ, which I gave in my series of articles during 1882. By the time apple trees were in bloom, the queen had brood in 12 frames, and from that source I extracted 16½ lbs. A few days after this, the 12 frames, bees and all were set into a hive 4 feet long, and a division board placed at the rear of the combs. Once a week two more empty combs were inserted in the centre of the brood-nest, until the hive contained 20 combs well filled with brood. As white clover was now yielding honey, the hive was filled out with frames of empty combs, which numbered 32. I did not expect the queen would occupy any of these last 12 combs, but in this I was mistaken, for before white clover was through yielding honey, I found brood in every one of the 32 combs, which, if placed compactly together, was fully equal to 15 frames full of brood. Each frame gives 100 square inches, and each square inch gives 50 worker bees, hence, there were 5,000 bees to batch out of each of these frames every 21 days, or 75,000 from the 15 frames.

The average life of the bee, in the work season, is 45 days, hence, it will be seen that the queen can place two and one-seventh generations of bees on the stage of action, to where one generation dies off. Two and one-seventh times 75,000=160,700, as the number of bees in that hive during the basswood yield. It was a sight worth beholding when they were just starting for the field in the morning, for they would rush out like an army, and then, later, the entrance would be one living mass going to and fro. From clover, they gave 186 lbs.; from basswood, 287½ lbs., and from buckwheat, 76 lbs.; giving 566 in all. Now, if we were to call 20,000 bees a colony, this would give but about 71 lbs. per colony, and I do not think either of the correspondents would be willing to call that an exaggerated report.

Thus, it will be seen that all these conflicting reports can be harmonized, when we understand how many laborers there are to perform the work. As I have said before (and it will bear repeating), the main secret in getting a large yield of honey, is to get plenty of bees, just at the right time to take advantage of the honey harvest. If you understand your location, and get your bees as above, you will have no cause to complain of your yield, if the flowers secrete honey.

Borodino, N. Y.

[Reports had been "going the rounds" simply stating that from 800 to 1,200 pounds of honey had been obtained by one colony in Texas or

somewhere else. No matter what explanations were made when the report was given, the statement was divested of details, and reiterated as "a good story" to tell, being so unreasonable that no one would believe it. Of course, it was understood that it was an *ordinary* colony; this led Mr. McKennie to figure it out (in his letter on page 60), and that "figuring" we desired to correct in our foot note, by saying that such colonies were "doubled up to the capacity of 4 or 5 ordinary hives, by extra stories, one over another"—that the colony was *not* an *ordinary*, but an *extraordinary* one! It will easily be seen that to those laboring under the idea that a colony of the usual size was spoken of, the statements were "unfair," "misleading," and "unreasonable." This was the idea we intended to convey, but, perhaps, we were not sufficiently explicit, and have, therefore, been misunderstood. We certainly never thought of reflecting upon any one's report, as some have presumed. We hope this will be sufficiently clear and satisfactory.—ED.]

For the American Bee Journal.

Moving Bees on a Hand Sled.

G. F. WILLIAMS.

During the fall of 1880, about two weeks after our severe winter began, I moved 9 colonies from my father's, a distance of two squares, on a hand-sled, to my own home.

The entrances were partly clogged with ice, and the bottom boards were very icy. So, thinking it best to give them a nice, dry one, as well as to protect them above, I carried them into the kitchen, removed the bottom boards, putting dry ones in their places, put a piece of thin cloth over the frames of each, on which a chaff cushion was placed, using during the operation, a smoker, when necessary, to keep the bees in the hives.

Eight of these were carried into the cellar and one put out of doors, protected by placing a store box over it, and filling the intervening space with sawdust. Of the 8 in the cellar, only 1 seemed to suffer harm from the moving; large numbers dying and clogging the entrance, which was removed about every week.

Early in March, they were all carried out for a flight, and again put back. Towards the latter part of March, they were again carried out for a flight, and not one returned. The one spoken of above and two others soon dwindled, leaving plenty of brood and eggs. The one left out all winter came through strong and healthy.

I am of the opinion now, knowing little of bees then, that if I had not removed them from the cellar for three or four weeks, two would not have dwindled.

Farmers about here, who wish to move bees, always move them in the winter. It is now a wonder to me, since I have read up on improved bee-culture, that any of the 9 lived through the long and tedious winter, and I hope no one will be so unwise as to move bees until warm weather. I, for one, shall not, at least until we have a great deal more knowledge of the "busy bee" and dysentery.

Central Illinois Convention.

The Bee-Keepers' Association of Central Illinois met according to previous announcement.

A large number of bee-keepers of McLean and adjoining counties assembled at the surveyor's office, in the Court House, in Bloomington, on the 10th inst.

Officers elected for one year: President, J. L. Wolcott; Vice President, Mrs. F. A. Baller; Secretary, James Poindexter; Treasurer, O. Barnard, all of Bloomington.

Owing to the lateness of the hour appointed for the meeting, the time was principally occupied in perfecting an organization and getting the Association in working order.

Thirty-two names were enrolled. It was decided to hold meetings quarterly. Adjourned to meet the second Wednesday in May (9th), at 10 o'clock a. m., in Bloomington, at same place.

JAN. POINDEXTER, Sec.

The Eyes of a Bee.

C. THEILMANN.

In examining the heads of bees with the microscope, I found the sides, which appear to the bare eye as if the high brown spots were the eyes, but found these two spots, all thinly covered with hair, without any glassy, bright or clear spot whatever, and the skin or outside covering appears like grained leather, when looking with the bare eye. Looking closer, with head three little, round, glassy, skinny the microscope, I found on top of the spots, one in the centre, a little ahead of the two, which are one on each side; there are no hairs close around these spots, but a bunch of hair between the three, and the head has to be held in a certain position, in order to see all three at once. If these three spots are not the eyes, where are they? I have examined spiders heretofore, and found from four to six of such little glassy spots on their heads, which I would call eyes.

My bees have been closed up now for over three months, without a flight, as it has been cold ever since, with over 2 feet of snow, and for the last six weeks the mercury has registered from 10° to 40° below zero, in the morning, except the last few days, when it showed 32° above. My bees outdoors (30 colonies) need a flight, as some of them have the dysentery. My

130 colonies in the bee-house got a little uneasy, these warm days, as the temperature in it went up to 65° with ventilator all open, and the main door open, its whole width, one whole night. This morning all is quiet, as it is 13° below zero outside; no dysentery appears in my bee-house yet.

Theilmanton, Minn., Feb. 17, 1883.

[The large eyes which you saw without the microscope, are the compound eyes; the three small ones are the

simple eyes, as shown in the accompanying engraving of the head of a worker bee, magnified.—ED.]

For the American Bee Journal.

The Standard Langstroth Hive.

M. M. BALDRIDGE.

Having shown on page 55 of this JOURNAL that the standard Langstroth frame is 18 $\frac{3}{8}$ inches long instead of 18 $\frac{5}{8}$ inches, outside measure, I now desire to say a few words about the standard Langstroth hive. The standard hive, as I understand the matter, should have 10 standard Langstroth frames—no more and no less—that being the number given and recommended by Langstroth in his work on bees—the highest and only authority to follow. Now, Langstroth makes the hive, or outside case, to hold 10 frames, precisely 14 $\frac{1}{2}$ inches wide, inside measure, but I find, in practice, that it is not necessary to make exactly that width of hive for 10 frames. I make the hive 14 inches wide to avoid the fraction, and find many times that I can use even 11 frames just as well as 10 in that width of hive. In fact, the combs will, other things being equal, be built straighter and nicer with 11 frames than with 10. I therefore find that a hive 13 $\frac{1}{2}$ or even 13 inches wide, inside measure, will answer for 10 frames, but to have Langstroth hives, of standard size, we must adhere as closely as possible to the length, width, and depth, inside measure, as given by Mr. Langstroth, or else we may as well quit talking about standard hives.

But there are quite a number of bee-keepers in the United States and elsewhere, who are to-day far in advance of Mr. Langstroth, in some respects, in practical experience (and when I say this I mean no disrespect to Mr. L.), who prefer the 8-frame hive, with standard frames, to the 10-frame hive. They have used both sizes of hives, side by side, in the same

apiary, and claim that they have uniformly secured better results from the smaller hive. Now, that being the case, it is folly and waste of time to try to induce all bee-keepers to use the Langstroth standard hive, although they might be willing to use the standard frame. From what has now been said, the reader will please observe that the standard hive and the standard frame are by no means synonymous terms.

It has been suggested that bee-keepers should hold a convention to see if they cannot in some way agree upon some standard hive to adopt. Now, to simplify matters, let me suggest that it might be far better, and less expensive, for bee-hive makers to agree among themselves to make the standard Langstroth frame of the same length and depth, both outside and inside measure, and the outer box or case of the same length, depth and width, inside measure, the width depending on the number of frames to be used, whether that be 8 or 10, more or less, the main object being to make the frames interchangeable. Bee-hive makers are the proper parties, so it seems to me, to agree upon such matters, as Tom, Dick, Harry and old-man Bungler have no more business to make bee hives, honey boxes, foundation, hives, etc., of modern construction, than has the former to make wagons, reapers, threshing machines, etc. As a rule, every branch of business is, or should be, carried on as a specialty, and bee-culture is, or should be, no exception. Bee-culture, however, has several distinct branches, and there are men so organized as to carry on two or more of them at the same time very successfully. But, in general, it will not pay bee-keepers to try to run all the branches as specialties at the same time. That being the case, the majority will find it better and more profitable to purchase certain supplies for their apiaries from specialists. I may be mistaken about this, but think not; it having been my experience for nearly a quarter of a century. And, to get the best results, two or more bee-keepers should club together in ordering supplies, and thus secure the lowest possible prices.

As I am not now engaged nor interested in furnishing "supplies for the apiary," and do not again expect to be very soon, it will not, therefore, be necessary for any one to impute improper motives to any of the statements set forth in this article.

St. Charles, Ill.

For the American Bee Journal.

System in the Apiary.

A. E. FOSTER.

"A place for everything, and everything in its place." I know of no place (unless it is in the family) where this rule should be followed more closely than in the apiary. The prosperous bee-keeper is always in a hurry, needing different supplies as he examines different hives, and it is very necessary that he should know just where to find things as he needs them.

If you have not this faculty well developed, cultivate it, by assigning everything in your apiary a place, and keeping everything in its place. The time lost in hunting "here, there and everywhere" for what you need, will amount to a great deal, more than any one would suppose; and it will not only save time, but keep you from getting in a bad humor, which generally follows one of those long searches. The mother who teaches her child to put things where it gets them, does the child good, and saves herself much trouble, in picking things up after it.

My bees are wintering well on the summer stands.

Covington, Ky., Feb. 14, 1883.

For the American Bee Journal.

Moving Bees in Winter.

R. M. DENHAM.

As some desire instructions about moving bees, and having had a little experience in the matter, I will tell what I know about it. I purchased two colonies of bees in box hives, of a neighbor, in the winter, and desiring to move them, when the snow was on, I put into the sled bed an armful of hay on which to set the hives. Some time before this, I had read Quinby's "Mysteries of Bee-Keeping," in which I found instructions on this point, and I desired to follow him. He said, when moving bees (in box hives), turn the bottoms upward, and place a sheet or something of that kind over the hives, to keep the bees from flying. My neighbor was an old man, and had kept bees (in box hives) many years, and, of course, thought he knew more about how to manage the thing than I did; consequently, he pushed the hay to one side and set the bees flat on the bottom of the sled bed, bottom down. I suppose he thought it would not be wholesome for the bees, to turn their heads down. I said nothing, however, but started home. The road was quiet rough in places, and the bees were considerably jolted, drive as carefully as I could. I had not gone far until I discovered that some of the combs were broken; this was a swarm of the previous summer, and the combs were tender and easily broken, and before I got them home, the combs were all broken off, and the whole "business" was lodged in the bottom. The other hive, being full of old combs, stood the jolting without breaking. This cured me of ever again hauling bees on a sled; though, I believe, had Mr. Quinby's instructions been followed, the combs would not have been broken.

Of course, moving bees in frame hives is a different thing, as the bottom bar, if the combs are built down to it, support them. I would always haul bees, short distances, in a spring wagon, and place the hives so that the combs would stand crosswise with the bed. I have moved bees this way, in the honey season, without damage.

This winter, in this locality, has been quite favorable one for bees,

when they had sufficient stores, as the thermometer here has not been below zero. I gave my 12 colonies sugar-syrup, made from the best grade of coffee A sugar, sufficient to winter on, and they are doing very well. I placed 8 of them in a clamp, and left the rest on the summer stands.

The future prospects for bee-keepers here are, I think, good, as there is an excellent crop of white clover on the ground, and we usually have a good crop of locust bloom, which comes in shortly after fruit bloom.

St. Clairsville, O.

For the American Bee Journal.

Sections, Separators, Etc.

F. C. BENEDICT.

It is with interest that I read the different articles on half-pound sections, separators and their use. It seems to me that a novice or any one who contemplates their use would be so confused they would hardly know whether there was a size known that would hold the required amount. Some talk about narrow sections and straight combs, without separators. Let us look into the brood chamber of a good colony and see the combs. Straight! Yes, beautiful combs as I ever saw; take the same combs after a good honey flow, and how are they? Instead of being $1\frac{1}{2}$ inches thick as we would like them (and about the thickness we find them when left to their own ways), the bees have built the top of this one a little thicker, contracted the next, no two straight and perfect. Why! because there are no separators to guide them, and they will expand one and contract another. Now, this will be found the same in the surplus arrangement, and let the section be so narrow that they must make their combs less than $1\frac{1}{2}$ inches, and greater will be the disappointment to those who shall use what might well be called the wafer sections, without separators. Some of the sections will be so thin they will be of no value, while others will be built into sections adjoining, making it hardly possible to get them in marketable shape. The only safe way would be to carry them single-handed and place them upon the consumers' table.

Some may think me taking a bold stand, when I state that I hold, that no one (I care not who) can manipulate 100 colonies of bees for comb honey, and produce it in first-class marketable order, whether it is to be glassed or unglassed, without the use of separators of some kind. Some contend that separators lessen the crop of surplus, but it is only a delusion under which some labor who are not up to the times in producing comb honey in perfect shape by the right use of separators. I know of what I speak.

A short time since I was upon the market of one of our large cities, where I saw tons of honey, and upon the cases I saw the names of some of our noted apiarists; nearly all were from the West, and produced without separators, and put upon the market

without glassing. All were leaking more or less, some so badly that the honey had run from top to bottom of the piles and granulated in streams as large as your finger. Why! because some of the combs were over thick, and chafed in the cases. Now, had the producers of that honey done their part, as well as nature and the bees did theirs, they might have realized 3 to 5 cts. per pound more for their product. This would far more than pay all expense of putting it upon the market in first-class order, rather than third or fourth class, as was some of the above.

Now, if we are to use half-pound sections, why not let those who contemplate trying them make a section that can be used to good advantage with the surplus arrangement at hand, and not be to the expense of new racks, frames, etc. If we must have different-sized fixtures for each sized section, what a collection of unnecessary traps will soon be on our hands. After three years' experience I find that a section, to hold $\frac{1}{2}$ lb. of honey, must contain $17\frac{1}{2}$ cubic inches, whether one thickness or another. Then adjust your section to your surplus fixtures on hand. Have your 1 and 2-lb. sections the same height, so that you can use the same width separator for both sizes. In short, have just as few extra fixtures as possible, for it increases the expense and takes off the profits. I manipulate sections in racks, and one-sized rack answers for the 3-sized sections with only extra separators for half-pound sections; one sized shipping case for 1 and 2-lb. sections.

Perry Centre, N. Y.

For the American Bee Journal.

Wood Separators and Bee Glue.

C. R. ISHAM.

In the BEE JOURNAL (page 95), Mr. James Heddon, in an excellent article on Surplus Cases, etc., makes the following request: "I wish Mr. Isham would send me a sample of his wood separators, and tell us, through the BEE JOURNAL, how he puts up with or avoids the glue difficulty spoken of above." I have sent Mr. Heddon a sample, for practical experiment, and the readers of the BEE JOURNAL will get the full benefit of his conclusions. As to "gluing up the less than bee spaces," I would say, as this space, when tin is used, remains open until closed with propolis by the bees; that it is not any more work to scrape off a thick than a thin chunk of glue, consequently I do not find much difference in cleaning the sections, whether thick or thin separators have been used. Those $\frac{1}{8}$ inch in thickness (and also, if desired thinner ones), can be notched out so as to come down to the bottom and yet let the bees pass up. In my own arrangements I prefer to have pieces cut from separator material of just the proper size, they being of same thickness (1-16 of an inch), to fill spaces at ends of the sections above the separators, for, when the rack is filled and clamped, they

can be quickly put in place, and you have a neat job, with all outside spaces nicely closed.

After putting the rack or case upon the hive, have a piece of enameled cloth, cut the proper size, to smoothly lay over the sections, and on top of the cloth place a quilt or piece of burlaps, and cover all with a flat board, fitted for the purpose. You now have a chamber for surplus storing which fully meets all the requirements of warmth, so necessary for comb building, early or late in the season, and violate no "scientific principles laid down by Langstroth."

In a case of sections thus arranged, the combs are of even thickness, with a smooth face, which gives the honey a much finer and more attractive appearance than when dented and bulged, as is likely to be the case where metal separators are not used. As wood is warmer than metal it economizes the heat of the hive which is the first great principle to be taken into consideration in making arrangements for obtaining surplus honey.

Peoria, N. Y.

For the American Bee Journal.

Was That Bad Advice?

DR. G. L. TINKER.

It is really bad advice, or rather, it is impracticable to set a rack of the thin sections down on the brood frames? Mr. Heddon so implies, see page 95 of the BEE JOURNAL, and expresses great "surprise" that I should give such advice. Now, I am not less surprised that a man of the experience and ability of Mr. Heddon as a practical bee-keeper, should "warn all beginners" against the advice, giving as his objections to it that he had "been through the mill and graduated," and that it would be "violating the instincts of the bees," and be resented by "their glue and stings." Surely, it is not against the instinct of the bees to have continuous passage ways from the brood combs into the sections. Neither can there be any trouble of any consequence on account of propolis, nor special danger over any other plan because of stings.

Several apiarists of large experience have assured me that the plan suggested on page 72 of the BEE JOURNAL, is thoroughly practical. Not only so, but it is quite possible that in no other way can the half-pound section be made to pay the producer.

The writer has not taken a fancy to the half-pound sections with a view to using them by any of the ordinary methods in use for getting comb honey in the 1 and 2 pound sections. On the contrary, it seems to me that its failure as a financial adventure to the producer by these ordinary methods, is already a foregone conclusion.

There are other advantages from placing a rack of sections down on the brood frames than those already given, and among the first of these is the readiness by which the bees can be got to work in all of the sections at once. This is accomplished by putting on the first rack of sections with

a narrow strip of foundation fastened upright to the bottom of the section instead of being fastened to the top piece. The bees will go to work in the sections the instant there is enough honey coming in, and build the comb upwards, which they seem able to do just about as fast as to build it downwards. The next rack of sections may contain full sheets of foundation, if it is desired, and fastened to the top of the section as usual.

New Philadelphia, O.

For the American Bee Journal.

New Method of Wintering Bees.

JOHN E. VAN ETTEN.

Any one can get along with bees in summer, but the great problem is how to winter them successfully; and for want of appliances, if for no other reason, out-door wintering must ever prevail with the million.

Some advise that bees should be placed in a cellar and kept dark. I tried this in a very dry, sandy cellar, with a cement floor, and yet with very disastrous results, arising from dampness and mold, which I find to be the greatest enemy of bees, especially in winter.

Others advise that they should be placed on the north side of a building or fence, so as to exclude the sun, and thus prevent them from flying out and becoming lost. I have also tried this with very fatal results.

Others advise placing them low down on the ground and letting the snow drift over them. This is sure death from the dampness generated from the melting snow.

Others advise covering with enameled cloth, packing in chaff, etc. These are all objectionable, because they absorb and hold dampness, which is dreadfully fatal to bees in winter, while they are in a dormant state and unable to ventilate the hive in their own natural way.

After years of trial I became convinced that all such theories were vicious and wrong in principle, and contrary to the natural requirements of the bee; that cold was not so much an enemy of bees in winter as dampness; that instead of being placed low down on the ground or in some bank, where all the dampness could be thrown into the hive, the hive should be elevated so that the winds could sweep away such dampness as might gather around it; that, instead of being kept dark in winter, the bees should have all the sunlight possible; that, instead of being placed in a shaded spot on the north side of a building or fence, they should stand on the south side, where they could receive the full benefit of the winter's sun—which, of all seasons, the bees most need in winter.

Acting upon these ideas, I placed my bees in the warmest spot I could find on the south side of a high, tight-board fence, where the full blaze of the winter's sun could pour down upon them. I elevated the hives about 2 feet from the ground to avoid the dampness, and gave them all the

ventilation which the Quinby hive will admit of. I discarded the enameled cloth, and, instead, covered with lath, which will not warp. On these I laid a mat of woolen cloth. In front of the fly hole, on flying days, I placed a portable box 2 feet long, 14 inches wide, and 7 inches high, covered with wire cloth, and, since then, I have never lost a colony. There is no dampness, no mold. If the bees want to fly, they fly around in the box, where they void themselves and receive the full benefit of the sun, and yet not a bee is lost upon the snow.

Kingston, N. Y., Feb. 2, 1883.

For the American Bee Journal.

Short Articles Always Preferred.

REV. A. SALISBURY.

We live in an age of revolution and progress. Revolutionary, in not using many words to express a few ideas; progressive in using few words to express many ideas. Why do short articles get the preference of readers in newspapers and magazines? It is not supposable that any one will pen an article without an idea, so all who have much to do in this busy world read short articles first, where they can glean ideas fastest, and where "counsel is not darkened by a multitude of words."

O, the horror, after having spent the time to read a long article, and the discovery is made, at the close, that it was words almost without any ideas.

True, there is an apology for those who labor under the conviction that the world is depending on them for light, so duty requires them to write many and long articles. Words are cheaper than ideas. Do not think that reflections are only to be cast upon the literary world, outside of our profession; like others, we are liable to fall into certain channels, and write and rewrite the same ideas, over and over, and occupy a long time in explaining ourselves, so as to be understood, and when understood, no one is benefited.

Camargo, Ill.

For the American Bee Journal.

Suggestions About Small Sections.

JAMES F. LATHAM.

To make a half-pound section, kerf a one-pound section on the inside of the top and bottom. Let the kerfing be wide enough to admit two pieces, each as thick as the sides of the section, and deep enough to leave 1-16 inch of whole wood on the outside. Cut two pieces, of a sufficient thickness to fill the kerfs, and in width corresponding with the sides of the section. Place the two pieces together and push them into the kerfs. A brad may be driven into the ends of each piece, if thought necessary. Put a piece of foundation in each half-section, and after the bees have filled them with comb and honey, they can be handled and crated as expeditiously

West Cumberland, Me., Feb. 9, 1883.

Two days after placing the frame in front of the hive, I examined the bees, and found about 3 square inches of comb filled with sealed brood, and enough bees to cover 4 Gallup frames.

The bees would fly inside the frame when the weather was too cold for bees in other hives to venture out, but I noticed the bees bumped themselves pretty hard against the glass when flying, and think they wore themselves out sooner than they would if the cold frame had not been there. They dwindled away so there was only about one-half as many bees and less brood on the first of May than there was when I first examined them. As I lost 5 other small colonies by the cold weather and dwindling, perhaps the cold frame had nothing to do with their dying.

My experience with mignonette, the past season, was as follows: First, it will not succeed under the shade of apple trees, if you give it the best of care. Second, it must be kept free from weeds. Third, it must be sown early, so to get a good start before dry weather sets in. I sowed the seed on different dates, from May 27 to June 19; the first sown did well. I sowed it in rows, covering the seed about $\frac{1}{4}$ of an inch deep. The plants spread out about $1\frac{1}{2}$ feet on either side of the row. They commenced to blossom May 27, and increased in bloom till August; and did not get through blossoming until freezing weather. The bees worked on the blossoms all day, and in all kinds of weather, when they could fly. They gather large quantities of pollen, but I do not know how much honey they get from it.

Wired frames seem to be the best for fastening comb foundation to, but the wire bothers in many ways. For example: The bees will often build queen-cells over them, and if you wish to save the cells you must cut the wire; then, again, in scraping wax and propolis from the top and bottom bars of frames, the wire hinders the operations. I have found the following a good way to remedy the difficulty: After the foundation has been all drawn out, and the honey in the comb extracted, cut the wires at the bottom of the frame, take hold the end of the wires (one at a time) and pull them backwards to the top bar, and then through it. They can be taken out quite fast; the wire cuts a slit through one side of the comb, but does not remove much wax, and the bees soon draw it together again.

I was surprised to see the following statement, which I clipped from the *American Cultivator*: "The flowers of raspberries, where this fruit is largely grown, are ruining the honey product of the neighborhood. The bees like this food, but no human being has been discovered who appreciates the product. The honey from raspberry flowers is a dirty yellow in color, with a very disagreeable flavor." The honey gathered here, when raspberry bushes are in bloom, is nice, but I do not know how large a percentage of it is raspberry. Will some bee-keeper, situated where there is an abundance of raspberries, please report upon this question.

Nantick, Mass., Feb. 5, 1883.

Attention is called to our new and liberal advertising rates for 1883.

SELECTIONS FROM OUR LETTER BOX

Foundation with High Side Walls.

I mail you, for the BEE JOURNAL museum, a sample of comb foundation made on my mill, that I think is the highest side wall ever raised by any mill.

WM. C. PEHLAM.

Maysville, Ky., Feb. 8, 1883.

[It certainly has the heaviest side wall we ever saw; the cells being deep enough to be utilized by the queen for receiving eggs, just as they are.—ED.]

Changing to Other Hives.

I have 3 colonies of bees in American hives, these being the hives most used in this section. I have read a good deal about the Langstroth hive, but have never seen one. Would you advise me, as I have started with the American, to change to the Langstroth? Some bee-keepers here prefer the American hive, on account of the frames being deeper, and say the Langstroth frame is too shallow for this section for safe wintering.

A SUBSCRIBER.

Milan, N. Y., Feb. 16, 1883.

[Certainly not. Success depends much more on the management than on the kind of hives. Beginners should not change around, or have different sizes of frames. Begin right, stick to what you have commenced with, and "go-ahead."—ED.]

Profitable Increase.

Here is my report for 1882: Apiary No. 1.—Spring, 1882, 6 colonies, fall, 1882, 14 colonies, average comb honey, spring count, 63 lbs.; apiary No. 2 (on shares), spring, 1882, 12 colonies; fall, 1882, 12 colonies; average, comb honey, 30 lbs. These figures demonstrate to me, that, at least in my locality, a judicious increase is profitable. All these colonies were substantially in the same condition on May 15, viz.: starving. I fed all alike with the above result.

F. C. GASTINGER.

Ada, O., Feb. 11, 1883.

Comb Honey Rack.

I sent to the museum a sample of my improved comb honey super, with 28 $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ inch sections. It is made for the 10-frame Langstroth hive, but may be made to suit any sized hive or sections. It can be used with or without separators. It is a second story, made to suit the size of the section to be used. The sections are to be placed in broad frames, without tops. They are strong, very simple, and easily manipulated. They can be tiered up, one above another, or two of them may be put on the hive at once, a frame of sections removed from each, and a frame of brood put in its place, to cause the bees to commence work in sections. If 56 sections, or 48 after

8 are removed, is thought to be too many, early in the season, the bees may be excluded from a part of them by simply turning those not to be used in the lower super on their sides, or putting a piece of picture backing, or cotton sheeting, under them, and using the wedges as division boards. The hooks holding the movable sides are too small, but are all I have on hand.

A. J. HATFIELD, 57-88.

New Carlisle, Ind., Feb. 17, 1883.

[The Rack is received and placed in the Museum. It is so well described by Mr. Hatfield that it is useless to add anything to it.—ED.]

Preventing Increase.

Having now 283 colonies of bees, I do not desire any increase, and intend to run them for comb honey; that, in the past, I could not do, without the swarming fever taking place and partly frustrating my plans. In the BEE JOURNAL, No. 40, July 26, 1882, page 474, I saw an article by Prof. A. J. Cook, on "Increase of Colonies Prevented." After reading that article I would like to put it to the test, but as my honey flow ceased about July 20, I had no opportunity to do so. I would like to ask, through the BEE JOURNAL, any apiarist who has tried that plan to kindly report the result. If it can be successfully done to the amount of 75 per cent. I shall be delighted, and I know I am not alone in this matter. Thus far, bees are wintering well.

J. B. HALL.

Woodstock, Ont., Feb. 10, 1883.

Bees Eating their Combs.

Two of my colonies of bees are eating their combs. One had about 60 lbs. of honey and plenty of pollen, and was in tolerably good condition, but it had no queen, and many bees were dead. The other colony had lots of frost in the hive, and was in very poor condition, but it had a queen, and though the bees were not dead, they could not fly in the sunshine. What is the reason for their doing so?

M. M. SPERRY.

La Harpe, Ill., Feb. 13, 1883.

[While bees cut their comb for various purposes, such as making passage ways, shortening the depth of cells, etc., they do not eat it. They often cut and drag out excess of bee-bread.

The second colony mentioned, if not starved, is, very likely, badly diseased with dysentery, though the outward symptoms may not have been observed by you.—ED.]

More Encouraged.

Since writing my letter, published on page 109, my bees have had a flight. I have cleaned out the dead bees from the greater part of the hives, and I find that some have commenced breeding. They have a great deal of pollen, but I think they will get through all right, if the weather is not wet and cold too long.

S. VALENTINE.

Hagerstown, Md., Feb. 16, 1883.

Cellars Safest for Wintering Bees.

I commenced the spring of 1881 with 1 colony, received 75 lbs. of surplus comb honey, besides leaving a good supply for winter; had 1 swarm come out, but it went to the woods. I bought 5 colonies the following spring, increased to 15, and have taken over 400 lbs. of surplus. I am wintering part in cellar and part in chaff hives. I think those in the cellar are doing the best, but all are doing well. I have about 75 lbs. of wax, which I want worked up for my own use. When would be the proper time to have it worked in order to have it fresh, and when ought I to commence giving it to bees to draw out for my young swarms? T. S. JOHNSON.
Bogart, O.

[You should get it made up soon, so as to have it on hand when you want to use it, which will be in the spring. Insert a full sheet in the centre of the brood nest only as fast as the bees will use it. All that depends on the weather, and the honey flow.—ED.]

Chaff Packing Eaten up by Stock.

On Jan. 18 and 19 we had a blizzard that has made havoc among our bees. It was 20° below zero, on the 19th; on the 31st it again started at 10° below zero, and has been cold up to the present date. Most of the bees are wintered on the summer stands, packed in sawdust and chaff. One thing with our wheat chaff: the thrashing-machines do not take all the wheat out of the straw and chaff, and it becomes a harbor for mice, and they disturb the bees too much during the cold weather. One of my neighbors had his bees packed in the old style of stack bive, with corn fodder, and an old cow just feasted on the fodder until she had bared the most of his hives, and it is much the same with lucern chaff, if the calves get into the lots where it is, they will be around all night disturbing the bees and eating the lucern. JNO. DUNN.

Tooele City, Utah, Feb. 12, 1883.

The Half-Pound Section Craze.

There seems to be a great deal of enthusiasm displayed, for the past few weeks, by some, in trying to invent a half-pound section. While I admired the good judgment, used by some, in determining the proper size and dimensions most desirable for such sections, I must say that it seems to me as if they are directing their energies in the wrong way to aid in the profitable production of comb honey at a reasonable price. I admit that if but a few of these half-pound sections were used, they might be sold for a price that would pay for the extra cost and trouble, but I predict that, if any are used, many will be used, for *this is America*; and few are willing to be outdone in extravagance, but the time will soon come when we shall be unable to sell these half-pound sections of honey for enough more to pay for the extra cost, which would be no small matter in large

apiaries, if we consider all the manipulations, preparing for market, etc. The retailer will want more profit, per pound, for the trouble of selling a half-pound package just as much as for a pound. This I know by experience, for in disposing of about 8,000 lbs. of honey, during the past season, I had a few cases of partly-filled sections, and as they were well finished, I sent them to a retailer who sold them out and found no fault with the honey, but said the per centage he received per pound did not pay for the trouble of handling, unless the boxes weighed 1 lb. each. Now, the question in my mind is, can bee-keepers afford to introduce anything smaller than one-pound sections? FRANK McNAY.

Mauston, Wis., Feb. 10, 1883.

Wintering Bees.

I have 24 colonies of bees; they are in the cellar, and are all quiet, as yet; the uncapped honey was extracted, so they have had capped honey to winter on. The hives I make myself; they are 20 inches long, outside, by 15 wide; frames run crosswise of the hive. I use 2 division boards, and winter the bees on 7 frames, and give them from 10 to 15 lbs. of honey to the colony, with a passage way through each comb. In the winter of 1880-81 I lost 1 out of 9; increased to 34, and sold 15. In 1881-82 I took 500 lbs. of extracted honey from them. (I had no losses in the spring of 1882.) From the 19 colonies remaining I got 1,000 lbs. of extracted honey and 200 lbs. of comb, and sold 10 colonies. I keep a thermometer in my cellar; it stood from 4° to 8° above freezing, except 2 or 3 nights, thus far. When the mercury was down to the freezing point, they roared. JOHN BENHAM.

Homestead, Mich., Feb. 16, 1883.

Never Lost a Colony in Winter.

The mercury is up to 66°, this morning, and I have just examined 2 colonies of bees, finding them in fine condition; one having brood in all stages. I can hardly miss the honey they have eaten; but since they have commenced rearing brood, the honey will go fast. I have yet to lose my first colony in wintering. J. P. MOORE.

Morgan, Ky., Feb. 16, 1883.

345 lbs. of Honey Per Colony.

I have hesitated for sometime to give, in the BEE JOURNAL, my success with bees in 1882; but reading of so many having large yields of honey, I felt that I was but a small bee man in the business, which I readily concede. I have been in the apicultural business some 16 years, using the Langstroth hive, and also a patron of the BEE JOURNAL, under the late Samuel Wagner, and always found it full of good logic. Last spring I had 5 strong colonies of bees (Italians and hybrids), to start with. The honey season was one of the best I ever experienced. From 5 colonies, I had 6 increase. One colony gave 2 swarms, and some of the others gave second swarms, but I removed all queen cells and surplus queens, and returned the swarms

to the present colonies. This stopped their swarming. I caught 4 traveling swarms by decoy hives, that contained a few sheets of empty combs, making my number 15 in the fall. My honey crop was 1,725 lbs., or 345 lbs. per colony, spring count. (955 comb, and 770 extracted.) Considering my explanations below, all will certainly give me credit for not exaggerating. Two years ago this winter I lost all my bees (35 colonies); leaving many good frames of empty comb, of which I took good care. As each of the 6 swarms came out, they were supplied with these frames, as also those caught in the decoys. There were but 2 colonies of the 15 but gave surplus honey. For me to claim (as some do) that all the honey comes from the first 5, would be unfair. This proves the great advantage to be obtained by taking care of all surplus comb, as well as benefits derived from foundation. Mr. Editor, does this explanation satisfy you that mine is a correct statement? I have nothing to gain by a misstatement, and nothing to lose by straight talk. H. W. WIXOM.

Mendota, Ill., Jan. 27, 1883.

[The explanation is sufficient; and would account for a large yield.—ED.]

More Light.

In the BEE JOURNAL, page 27, January, 1883, is a report from Mr. W. H. McLendon, Lake Village, Ark., headed "200 lbs. from 1 colony." After mentioning the amount of extracted and comb honey, he says, "as well as 200 lbs. of beeswax from 70 colonies in the spring, and increased them to 130, by natural swarming." Will Mr. McLendon be kind enough to explain, through the BEE JOURNAL, how he obtained the large amount of wax? It will gratify some who have kept bees for many years.

N. B. TINDALL.

Grafton, Ill., Feb. 8, 1883.

Bees in Dakota.

I started the season with 26 colonies, in fair condition, but owing to the cold rainy weather throughout May and June, I was compelled to feed my bees, to keep them from starving. I had no early swarms, my increase was obtained during the latter part of July and early in August. I only got 16 swarms, giving me 42 colonies to put into winter quarters; they were in good condition, and up to the present time are doing nicely. I took 2,200 lbs. of comb honey and 276 lbs. of extracted, making an average of 95¼ lbs. to the colony, spring count, which I consider very good for last season. I use a double-walled hive and winter on the summer stands. I will give you the result for the past 4 winters, as follows: In the fall of 1878 I had 5 colonies, and lost one during the winter. In the fall of 1879 I had 10 colonies, and lost none during the winter. In the fall of 1880 I had 22 colonies, and lost one during the winter. In the fall of 1881 I had 26 colonies; lost none. Last fall I had 42, and as above stated, have done nicely up to the present time; although

the weather has been very severe since Dec. 25. The BEE JOURNAL failed to put in an appearance this week for the first time since I became a subscriber. I have become so accustomed to it that I am lonesome without it; the snow blockade must be the cause. I hope it will make its way through, for its bright pages are as welcome to me as the smiling face of a friend.

W. M. VINSON.
Elk Point, Dak., Feb. 5, 1883.

Shipping Honey to England.

Please give a report of the proceedings of the Northeastern Convention, held Jan. 9 and 11, at Syracuse, in the Weekly BEE JOURNAL. I have been expecting to see it, as usual, and I have no doubt it will be interesting to all who were not there. Would you advise shipping prime extracted honey to England, next year? Can 10c. net, in bulk, be realized by shipping? Answer in BEE JOURNAL.

J. E. THOM.
Streetsville, Ont., Feb. 9, 1883.

[The proceedings of the Northeastern Convention have not yet been received from the secretary, or they might have been published.]

As to shipping honey to England, we advise you to write to honey dealers in that country about the matter of realizing 10 cents per pound, net, in bulk.—ED.]

All is Well.

The floods have done incalculable damage. On the 15th and 16th instant the weather was like summer; the bees roared as they do in the spring of the year. Our bees are safe, so far. The winter has been wonderfully wet and changeable. I feared the results, but—"all is well."

G. W. DEMAREE.
Christiansburg, Ky., Feb. 17, 1883.

Bee-Keeping in Virginia.

MY REPORT FOR 1882.—I ran 12 colonies for extracted honey; they yielded 4 barrels of honey, or an average of 116 lbs. to the hive; all of it sold at 12½ cts. per pound, making \$172.80. I had some 300 lbs. of comb honey in one-pound sections, which I sold at 12½ cts. per pound. I cannot sell one grade of honey here any higher than another. When a customer comes to me for honey, I sell him the kind he wants; if he wants it cut out of the sections and put into a bucket, I cut it out; if he wants it stirred up, I take a stick and stir it into a mush. The same 12 colonies that gave the 4 barrels, also gave 72 frames of honey, nearly all full and capped, which I took out late this fall. I do not know what they will weigh, but I estimate them, an average of 6 lbs., which would make 432 lbs.; this was gathered from asters in September and October. Northerners must stop saying that we cannot produce as nice honey in latitude 36° as they can in 40°. I will venture to say that Southwestern Virginia and Northwestern North Carolina produce as white

honey as anywhere on the globe. The most beautiful honey I ever saw was in Wilks Co., N. C. I do not know what kind of flowers it was gathered from, but I expect it was from sourwood. I have some honey that has candied, when put on the table you cannot tell it from light-colored butter. I have produced sections almost as white as snow. The flowers we get our honey from are as follows: The first to bloom in the spring are elm and willow; then comes locusts, whortleberries and blackberries; then poplar and white clover, which is very abundant; then follow linden, goldenrod and buckwheat; asters comes in September and bloom until cold weather. The mercury hardly ever goes below zero, so our bees never winter-kill, to any extent.

JOHN FARIS.
Town House, Va., Feb. 7, 1883.

Packed in Chaff—No Losses.

My 25 colonies of bees, that I packed last fall, in the Langstroth hives, are all right. They had a nice flight yesterday, and to-day I examined all of them; they have brood in all stages, and some young bees are crawling over the combs in several of the hives. I packed my bees on the summer stands, with wheat straw on the sides and back end of hive, and chaff cushions over the frames; and I never lose any bees in this way of packing.

A. T. KELLY.
Franklin, Ind., Feb. 16, 1883.

Lovely Weather in Florida.

The weather is lovely here now, just what is wanted during the State Fair. I have been out to the Fair twice, and find the display of fruits to be very good. The part of most interest to the readers of the AMERICAN BEE JOURNAL is the display of W. S. Hart, of New Smyrna. He has some of the finest comb honey I ever saw; it, and his display of extracted honey, cannot be beaten outside of Florida. Mr. H. also has everything necessary for successful bee-keeping.

H. G. BURNETT.
Jacksonville, Fla., Feb. 15, 1883.

Statistical.

I sometimes think it would have been better if the amount of foundation used by each bee-keeper had been included in the reports; mine would read as follows: 20 colonies, fall of 1881; 20 colonies, spring of 1882; 58 colonies, fall of 1882; 300 lbs. of comb honey; 2,300 lbs. of extracted honey; 10 lbs. of beeswax; and 100 lbs. of foundation used in brood frames. AUG. J. HINTZ, 20-58.

Lamont, Ill.

Too Much Sorghum.

Yesterday, the thermometer being about 45°, I walked out among my bees, and found two colonies flying briskly, daubing the entrance, front of the hive and alighting-boards. The others (20 in number), seem to be all right now, but I fear they have too much sorghum honey in the hives, as there were several crops worked up

in this immediate neighborhood, and thousands of my bees were destroyed in the boiling fluid. There has hardly been a week this winter that bees could not fly. I use the Simplicity hive, with division boards and chaff cushions, and the two that seem to have dysentery are better protected than the others, having a large box turned down over the hive. One of the queens is a perfect beauty; I obtained it from Mr. H. C. Hersperger, who, I think, has a very superior strain of bees, as regards docility and industry. I propose to test several of the better strains during the coming season, in an endeavor to find the best.

N. H. ROWLAND.
Keene, Ky., Jan. 31, 1883.

Mortality Among Unprotected Bees.

My bees, wintered on the summer stands, had a flight to-day, the first time since Dec. 23. I made a thorough examination, and I find many colonies in bad condition. They were packed in sawdust. Those in the cellar are wintering well. My neighbors have bees left on the summer stands, unprotected, and I looked over several of them, and I feel safe in saying more than half of them are dead. It has been very cold; as low as 36° below zero on Jan. 22; the snow is about 18 inches deep on the level, but it is raining to-night. I fear the mortality among the bees will equal, if not exceed, that of 1880-81. I hope Mr. Sorrick will call a convention at Des Moines, as he has suggested.

H. CLARK.
Palmyra, Iowa, Feb. 13, 1883.

Scarcity of Water in California.

The rain fall this winter, so far, has been only 22½ inches. Since 1878 the rain has been insufficient, consequently the surface of the country is very dry, and, in the mountains, the springs and streams are unusually low. The general appearance of vegetation shows the effect of the drouth. Last winter we had but little rain, until February. The bee-keepers of California were hoping for a wet winter, as a good honey yield generally follows such a winter. At present the prospect for the bee-keepers is not encouraging, and, unless it rains soon, California will not have honey enough to supply the home demand.

J. E. PLEASANTS.
Carbondale, Cal., Feb. 5, 1883.

Sowing and Planting for Honey.

I see many favorable reports of the honey crop for last year; mine was as favorable as any. As to the best honey plant, there is nothing that equals the basswood. Clover is also spoken of, as being first-class; I only consider it second-class for quantity, and that is governed by the season. Care should be taken to have plenty of bee pasture. To sow, plant and cultivate is the only way to make the business profitable. It is about time for nurserymen and seed men to advertise in the BEE JOURNAL, to get the bee-keepers at work preparing for the next spring. I shall want some-

thing of the kind, and desire to know where I can do the best. Bees in this locality are all right, up to this writing; if the spring opens fairly, the coming season, will be a prosperous one. I take my opinion from the condition of the soil. The freezes and dry weather have not destroyed any of the plants, as yet. I hope soon to see some advertisements of plants and seeds for the coming season, and also to hear of interest taken in sowing and planting—that prosperity may abound among bee-keepers.

THOMAS PRALL.

Carlisle, Iowa, Feb. 3, 1883.

Bees Uneasy in the Cellar.

My bees are in frame hives; some of them are covered with gunny or old coffee sacks placed on top of the frames and a board laid on top of that; one is covered the same way with heavy paper in place of the gunny; the others have a honey board that fits the top of the hive, and a cap that comes down over the top of the hive and shuts it up tightly. They are all well filled with honey, and are strong colonies. They are in a dark, dry cellar, and those that have the caps on are very uneasy, while those with the gunny and paper on are quiet. Should I take the caps off, and give the hives ventilation at the top? Would it do to put lights in the cellar, and let them fly in the cellar? How warm does it need to be for them to fly?

W. T. GREEN.

Union Pier, Mich., Feb. 16, 1883.

[By request, Mr. Heddon replies to the above, thus: "I should have to know further of the exact condition, in every respect, of the two classes of hives you mention, in order to account for the difference in behavior of the colonies. Try alterations of two or three of the uneasy colonies, and note effects? Often colonies are very uneasy and yet persist in wintering well. By no means give them any inducement to fly in the cellar, nor out-doors until the temperature is right. Let your cellar remain dark, and at such temperature as that in which the bees keep most quiet." If Mr. Green wishes any further answer than the above, he will please send particulars to Mr. Heddon.—Ed.]

Sending Bees South for Winter.

On Feb. 6, at about 4 p. m., a gentleman came into my office and said to me: "I am E. T. Flanagan, of Belleville, Ill." After reciprocated compliments, we went to the apiary and examined bees and queens, until it was too dark, when we returned to the office, and we got so interested in discussing bees, that it was nearly 9 o'clock when I thought of supper, after which we resumed the subject, and it was 2 o'clock in the morning when we thought of bed. Next morning, after showing him my steam factory, we went back in the apiary, and showed him how I reared queens,

and we also examined my 4 and 5 frame nuclei, wintering on their summer stands, etc. I am wintering 35 colonies of bees for him, which are to be sent back to him by May 1, increased to double and full of bees. He has taken with him 5 of the best, to Kennerville, La., so as to Italianize 100 colonies he has just bought there, and they are to be doubled up and sent back to him in May; he has a man there to attend to the bees, so that he will get about 250 to 275 colonies of bees in his apiaries at Belleville, Ill., by the middle of May, strong and in condition to gather a crop. He says that he intends to send his bees South every fall to winter, and have them returned double in number by the first week in May, and thus not run the risk of wintering, and have them home, etc. The cost of sending me the colonies were 50 cents each; they will cost no more to return, and as far as I can calculate, they will not cost him much over \$2.50 each, including the new queens for the division, etc.

P. L. VIALLO.

Bayou Goula, La., Feb. 9, 1883.

Had the Dysentery.

I put 70 colonies of bees, into winter quarters, well filled with winter stores; 50 of them I put into an outside cellar on Nov. 15, especially prepared for them, and they are doing well. Some of the 20, left on the summer stands, had the dysentery about Jan. 20; these I moved into the cellar, and it seemed to check the disease; as just as I saw symptoms of the disease I moved them in, until I have only 7 left on the summer stands. I see no more of the disease in those that I moved into the cellar. Will there be any danger of the disease spreading in the cellar?

M. H. LEWIS.

Green Top, Mo., Feb. 15, 1883.

[The cause having been removed, the effect ceases; there is no danger of the disease spreading in the cellar.—Ed.]

Expects a Good Season this Year.

My 107 colonies of bees, up to the present time, are in splendid condition; they were put in the cellar Nov. 15, 1882, and will there remain until natural pollen appears. I expect a good honey season, this year; last year was a very poor one, but there was a good demand for honey at 18 cts. per lb.

F. G. KINNEY.

Bristol, Ind., Feb. 22, 1883.

What Bees Get from Corn.

Bees had a glorious flight to-day; they flew from 11 a. m. till 4 p. m.; they commenced cleaning house, brought out some half-grown young bees. Every colony is alive and strong, one crawled up my coat into the back of my neck, and elevated me a trifle. What is the use of breeding any longer for the coming bee? Why not get some of the bees Mr. Stewart speaks of, that can split a corn stalk from end to end, and just flood the whole country with honey? I have

seen bees work in corn stalks late in the fall, after the corn was cut up and the sap oozed out of the stump, but that is all. They gather pollen from the tassels, early in the morning, and on moist, cloudy days. If bees can gather honey from corn stalks, there is corn enough grown in Illinois and Iowa to float the United States navy.

JAMES RONTAN.

Villisca, Iowa, Feb. 20, 1883.

Maryland—Bees All Right.

I took off the cushions from my hives and put one thickness of burlap over them. They came through all right, and had a good flight last Saturday. I put wire screens over the entrances, and to keep the bees from suffocation, by the entrances being clogged up, I tipped the hives back a little.

THOS. THURLOW.

Federalburg, Md., Feb. 19, 1883.

Symptoms of Disease.

Please give symptoms when the bees have dysentery. Do the feces look any different from the healthy ones? Some of my bees are very uneasy, and when they come out to the air, they eject a great deal more feces than others.

W. T. GREEN.

Union, Mich., Feb. 19, 1883.

[Yes; the feces are yellowish, and the bees soil the entrance and combs, their bodies being unusually distended. A good cleansing flight will remedy the difficulty.—Ed.]

Bees Gathering Pollen.

My bees are all very strong in numbers, and are gathering pollen rapidly now, and the queens are filling empty combs with eggs.

R. J. ADAMS.

Lakeport, Ark., Feb. 16, 1883.

Cold, but Bees are Comfortable.

We have had a very cold, changeable winter. The mercury has been 29 times at and below zero. On the 16th it fell 20° in 3 hours. On the 27th of last month it was 28° below zero. Our 84 colonies are wintering nicely in the house cellar, although it seemed impossible to keep it as warm as it should be; they keep very quiet, and show no signs of dysentery, and but very few dead bees on the floor.

S. L. VAIL.

Coal Creek, Iowa, Feb. 19, 1883.

Sealed Brood on Two Frames.

Last fall I packed 37 colonies of bees. Yesterday and to-day they had a good flight. I looked through 22 hives and found sealed brood on two frames; some hatching, and all doing well. Some I packed on the summer stands; the rest were put on a broad board, 6 inches apart, the spaces filled with straw, the hives faced the south, and they were covered with boards, extending well over the fronts; corn fodder was placed along, back of the hives (the north side). I see no difference in the bees, between those packed and the ones on the board.

WM. G. GOSNEY.

Demossville, Ky., Feb. 16, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Notice.—Bee-Keepers, we call your special attention to the advertisement of Champion Bee-hive Manfactory. 2t

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., February 26, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. here. BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, on arrival; 1 dark and off colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival. BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@c. to 14c. Extracted, 8c. to 10c., according to color. BEESWAX—32@33c. per lb. for good. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—For common qualities there is no demand. In a small way strictly fancy lots of either comb or extracted might be placed at an advance on quotations. White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9c.; dark and candied, 5@7c. BEESWAX—We quote 25@28c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16c., strained, at 8@7@7c., extracted at 7@8@8c.—lots in small packages, more. BEESWAX—Scarce, firm; quote choice at 28@30c., dark at 22@24c. W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 19@20c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 9@10c. in bulk and 11@13c. in cans. BEESWAX—Scarce, 29@30c. A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Choice to fancy white clover honey continues scarce and firm, but buckwheat and extracted honey slow and irregular. We quote: White clover, first quality, 1 lb. boxes, 24@25c.; fair to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c. BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly. Western pure, 30@32c.; southern, pure, 31@33c. D. W. QUINRY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels. BEESWAX—Our supply is gone; we have none to quote. CROCKER & BLAKE, 57 Chatham Street.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Convention Notices.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present. G. W. DEMAREE, Sec. Christiansburg, Ky.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews. WM. R. HOWARD, Sec. Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nelle's Corners on Saturday, March 31, 1883, at 11 a. m. H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883. S. W. SALISBURY, Sec.

The Eastern Michigan Bee-Keepers' Society, will hold its annual meeting in Detroit, April 3, in Abstract Hall, commencing at 10 a. m. An interesting meeting is expected, and bee-keepers are requested to send items or questions of interest to the secretary in time, that they may be announced previous to the meeting. A. B. WEED, Sec. 75 Bagge St., Detroit, Mich.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address (Prof. A. J. Cook), on Wintering Bees. Essays: S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested. E. N. Wood, Sec. North Lansing, Mich.

Articles for publication must be written on a separate piece of paper from items of business.

We have a few copies of our pamphlet entitled "Bee Culture" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

No. 10.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Half-Pound Packages for Honey.

In the report of the Eastern New York Convention, given in this paper (on page 131), it will be noticed that the meeting *deluded itself* with the idea that the editor of the BEE JOURNAL had conspired with Boston honey dealers, to force bee-keepers to use half-pound sections.

Our readers will, no doubt, *smile* (and perhaps *laugh* heartily) at the absurdity of that convention "making a man of straw, for the purpose of knocking him over." We, certainly, never had such a thought or desire, and do not see how any one could be *insane* enough to impute such a thing to us. The facts are these: While attending the Michigan State Convention, last December, at Kalamazoo, when the subject of "Sections for Honey" was being discussed, we made some remarks about conforming to the requirements of the trade, as to the size of sections to be used, and stated that some years ago people were satisfied with six-pound boxes, but in this progressive age they demanded *sections*, holding one or two pounds; and as a *fact* (or item of news), we stated that a Boston firm had, during the past summer, sold a lot of honey in half-pound sections—but we did not advocate their use, or request any one to adopt such a package! That this was the case is proved, beyond successful contradiction, by the report of the secretary, as published in the BEE JOURNAL, on page 792; which distinctly says:

"T. G. Newman remarked that he was not an advocate of half-pound sections; but, if they were used, they should have a large surface," etc.

Again, in an editorial in the BEE JOURNAL for Jan. 10, page 18, we used this language, in reference to the half-pound section:

The BEE JOURNAL would strongly advise *caution*. Let it be thoroughly discussed, and, then, let a few be tried and, if they will increase the consumption at good paying prices to the producer, then increase the dose, another year; but do *not* attempt to glut the market, else it may have the opposite effect.

Mr. Ripley (who is alike condemned with us) on page 35, remarks thus:

We have noted, with anxiety, the discussion about the half-pound section, and find that the demand is credited to come from Boston, and we want to set ourselves right with producers in the matter.

In the first place, we want it distinctly understood that we do not advise any one to use the half-pound section exclusively. Mr. F. C. Benedict expresses our views on the subject perfectly in your issue of Jan. 3. No producer can afford to use half-pound sections exclusively. One-pound sections are small enough to please 95 out of 100, and producers must respond in this proportion.

Notwithstanding all the caution, our remarks are *tortured to mean just the opposite* by that Convention, which, in its report, has published to the world "that Mr. Newman, editor of the BEE JOURNAL, should be *censured* for his officiousness, in writing and going about with Mr. Ripley, doing all he could against the interest of those to whom he looks for support."

That is *sublime*! Not only have we not written in favor of the adoption of half-pound sections, but we have *cautioned against* their general use! Nor did we go anywhere with Mr. Ripley, (or any other man), doing all we could either for or against any section!!

If those men had solemnly "*Resolved*" that we advocated "a return to black bees and box hives," were "making war upon all improvements in apiculture," defended the adulteration of honey with glucose, "to the injury of the producer"—and were sufficiently *insane* to believe that "the

moon is made of green cheese"—they would have been as near correct as the "statement" and "resolution" were, as published in their minutes.

Of course, the BEE JOURNAL has published discussions concerning half-pound sections, giving arguments for and *against* them. This is in the interest of progress and improvement, and if they are not to be used, discussion, free and untrammelled, will *kill* them; but, *if they are desirable* all the resolutions of conventions and anathemas of opposers, will be as chaff in the whirlwind, for

"Truth is mighty, and will prevail."

The article on page 802, so strongly condemned by the "resolution," gave the views of Messrs. T. F. Bingham, A. I. Root, James Heddon and Dr. C. C. Miller on the best size to make a section to hold a half-pound of honey. After giving their ideas, we remarked that the small sections (meaning those holding one or two-pounds) and the small pails of pure extracted honey had killed off adulteration, by placing pure honey within reach of the masses, and that "*any step* that will aid in *popularizing the consumption of honey*, and bring it into universal demand, will be welcomed by apiarists—no matter if it be a half-pound section for comb honey, or a five-cent pail for the extracted." This was a hint that such packages were among the *possibilities*, in creating a universal demand for honey, but did not in any way advocate their adoption. We cannot see, however, how any bee-keeper can object to the sentiment expressed.

We are well aware that men of influence or position are often subjected to misrepresentation and malignity (be it in religion, politics or science), but we had hoped (*rainily*, it seems) that bee men would not indulge in such *luxuries*! We have assiduously labored to popularize the consumption of honey, and thereby benefit producers, and to be misrepresented and maligned seems to be our reward!—Be it so! We accept it *as such*!

Electric Light and Electric Alarm.

—We have several times illustrated arrangements for electric alarms for the apiary. It now strikes us that the new electric apparatus can be made useful in protecting our apiaries. Concerning this new Lighter, the *New York Real Estate Chronicle* of Dec. 16, 1882, remarks as follows:

At last we can have the electric light where it can do the most good. That is to say we can put it now on our desks, on our tables, on our mantel-pieces, anywhere in fact where a clear, bright, safe lighter is wanted. The portable electric lighter, patented in 1879 and again in 1882, is now before us, and we look at it with surprise and happiness. Surprise, because it is evident how great a progress we have made in the science of electricity; happiness, because it gives us a clearer, better, more movable light than any we have ever enjoyed. Here is a lamp, so-called, occupying only the space of five square inches, which can be carried anywhere, and is besides an ornament. By simply pressing upon the knob to the full extent of the spring (which connects with the battery) an electric current is produced by which the spiral of platinum is heated to incandescence and the light is instantaneous. The material lasts about two months and can then be renewed at a small cost through any chemist. It will not be long before everybody will have a portable electric lighter. The price (\$5) is so low that it cannot fail to become popular at once. The principal office is at 22 Water Street, Boston, Mass.

Correspondence waiting to be published in the BEE JOURNAL has accumulated so much that we now have on hand all that can be accommodated for the next three months, and give our usual variety. This week several Convention reports crowd our columns so that we cannot give the usual variety. In one of the Convention reports some one intimates that we encourage Conventions in order to get matter to fill our paper—instead of this being true, we are seriously considering the necessity of omitting everything in such reports but the discussions that we may consider of value to our readers. The business portion is of but little interest to the general reader. We expect to be obliged to do this, to accommodate the growing interest in apiculture and its scientific unfoldment.

Those who have written for the Swede are hereby informed that he has gone to live with Mr. H. H. Overmyer, Lindsey, O.

The California *Apiculturist* has been suspended.

Flax Culture for the Seed and the Fiber, by Mr. H. Koelkenbeck, a flax grower and manufacturer of twenty-five years' experience in Russia, Germany, Belgium, Ireland and America, who is thus remarkably fitted for the preparation of such a work. American flax growers cultivate an area equal to about one-third of all the land planted to flax in all other countries, that is, about 1,127,300 acres. The value of the product is only about \$7.10 per acre, because of the shameful waste of the fiber. The value of the entire crop is but \$8,000,000, while the value of the fiber, from this area, if properly grown and cured, would be over \$40,000,000. Mr. Koelkenbeck tells us how this valuable crop may be saved, and the flax industry built up in America, by which we may save to home industry over \$200,000,000 per year, now paid to other countries for flax products. The pamphlet gives full particulars on cultivation, seed and saving the crop.

Some are getting impatient on not getting Alley's new book. We are promised a shipment next week. When they are received, all orders sent to this office will be filled at once.

CORRESPONDENCE

For the American Bee Journal.

How I Prevent After-Swarms.

JAMES HEDDON.

He who has learned the laws governing the habits of bees, from practice, as well as from theory, not only knows and owns, but feels the facts he has learned. The habit of swarming has been and is still deplored by many beekeepers, not only on grounds of extra labor of living, etc., but as detrimental to getting the largest yield of surplus honey.

You will notice, at the same time, that it "is not fair" for Smith to put his yield from one colony and its increase, against Brown's report of surplus taken from one that did not give any increase.

This plea was raised in *Gleanings* when I proposed to pit Mr. Vanderbilt's large yield of comb honey from one colony and its three swarms against a lesser yield of honey from Mr. Carroll's one colony, that did not swarm. Every man who objected, admitted that more surplus honey could be taken with, than without increase. This, I think, is correct, and just what I tried to show, some 8 or 10 years ago, but was then considered a

little too "fresh." Too much inclined to opposing the majority.

It is a fact, that the discovery of a practical, efficient method of controlling increase, would be a great boon to the keeper of many apiaries. As far as I know, no such system is known. I will proceed to give you a plain, simple method that I have used successfully for the prevention of after-swarms. Let us suppose that colony No. 14 swarms June 14. With a non-erasive crayon we mark upon the hive O, June 14, and on the hive in which we put the swarm, S, June 14. Thus, we distinguish the old colony from the swarm at a glance, as we make these marks in large figures. When we hive the swarm (always on full sheets of wired foundation), we place it close on the north side (our hives front the east) of the old colony, with the entrance turned northward, away from the old colony, about 45°. As soon as the swarm is well at work, having their location well marked (say two days), we turn the hive around parallel with the old colony. Now both hives face east, sitting side by side, and close together. Sometimes, however, being governed according to the size of the swarm, as compared to the number of bees left in the parent colony, we place the newly-hived swarm on the old stand, putting the old colony through the process above described. In fact, we do this most of the time. Now, you will remember, that while each colony recognizes its individual house, they are, at the same time, as regards all other colonies in the yard, practically in one location, or on one stand.

Now, the dates on the back ends of the hives plainly indicate that second swarming will take place in about 8 days. In about 6 or 7 days (according to season or weather) after this date on the hives, we remove the old colony to a new location.

As we do this at such time a-day as most bees are in the field, this depopulates the old colony, giving the force to the new, leaving too few bees for the young misses to divide, and as they at once recognize this fact, they fight it out on the line of the "survival of the fittest." It may be proper, just here, to say a few words regarding how we manipulate the surplus departments of these two hives, as it may have something to do with the object in view. Let us suppose that, at the time of swarming, that the old colony was working in three 28 one-pound section cases. Suppose the upper one to be $\frac{3}{4}$ completed, the middle one about $\frac{1}{2}$, the lower one just started. We will put two (which two, only the minor circumstances in the case can decide) on the swarm when first hived, leaving one, and, sometimes, we get another to put with it, on the old hive. Perhaps this surplus room on the old colony also has a tendency to prevent swarming.

I fancy I hear some one say, "What! all this surplus room over a swarm just hived?"

Yes, you see, but this article is not on how to produce comb honey, but the prevention of after-swarms, and while we think the success of the

above method will be quite clear to those who are familiar with the instincts of the bee, it will be further understood that the proper manipulation of the details is an important part, and can only be gained by experience. The success of this plan we know by experience, and its strong points are that it can be safely, surely and practically manipulated without hunting queens, or queen-cells, or even opening a hive. It only needs to be properly executed to be thoroughly appreciated.

Robbing the Inventors.

DR. E. B. SOUTHWICK.

I notice in the JOURNAL much talk about the "one-piece section," suggesting ways and means to get rid of paying the man that has introduced them, anything for his time and money spent in bringing them before the public, which is always more trouble than getting it patented. Prof. Cook also suggests that bee-men club together and have a friendly law suit, to see if the originator can hurt them if they do rob him. (I thought better of the Professor than that.)

The action of these men remind me of the boy that stole the apples. He saw a basket of nice apples in the corner of the fence. He saw no one near. He had nearly filled his pockets when a man, near by, asked what he was pocketing those apples for. The boy said he not know whose they were. The man replied, "you know whose they are not." So with all these men; they know that they have no right; the introducer has the right that is allowed to all nations, the right of discovery; and no man has any moral right to the thing, unless by agreement with the one that discovered it and brought it forward.

Suppose you unite and have a friendly (?) law suit, and beat; you will have the pleasure of congratulating each other on having the longest purse, being able to hire the biggest lawyers to pull the wool over the eyes of a jury. But that will be the pleasure of tyrants, in grinding down their subjects, because they have hired soldiers to do it.

I have no interest in, and I sincerely hope I may never become so insane as to desire to use the one-piece section.

Those who wish to manufacture or use the section, should take the advice of a man (who is not a Christian, but believes in doing right, because it is right); unite together and give Mr. F. a small royalty (say 25c. on a thousand more or less), for all that are manufactured in the next five years. That would give him a fair remuneration for time and money spent. How much better you would all feel if you were using a section that you knew had no dishonesty or injustice connected with it, anywhere; and that you were not liable to be drawn into a suit that would cost ten times what your sections were worth?

Mendon, Mich.

Bees in a Cellar Flooded with Water.

HARRIS PEARSON.

For the benefit of those who have wet or damp cellars to winter their bees in, I will give my experience. On Nov. 15, 1880, I put 40 colonies of bees into my cellar, which is very damp, with water standing in places around the bottom. The hives were put into a room 13x8 feet, and were raised from the ground 16 inches. The cellar is ventilated by a 3-inch tile drain, running 3 rods to its mouth, and a 1½ inch pipe passing from the bee room through the top of the cellar wall and up 12 feet on the outside of the house. The cellar was damp thro' Dec. and Jan., and I feared the result.

About the middle of February we had a heavy rain storm, which caused all low places to fill up with water.

The mouth of the cellar drain is near a sluiceway, which crosses the highway, which, being frozen up, the water could not pass through; consequently it backed up, the cellar drain filling the cellar to a depth of 16 inches, reaching to the bottoms of the lower tier of hives.

After about 30 hours the sluiceway thawed out, and the water disappeared, leaving the cellar as wet as it could possibly be. The hives remained standing as when put in, until April 15, 1881, when I carried them out, and found all colonies in good condition but two, and they had been destroyed by the mice.

I have now 65 colonies in my cellar; they have been in since Nov. 15; they are all quiet, and wintering finely.

Gouverneur, N. Y., Feb. 26, 1883.

For the American Bee Journal.

Sweet Clover not a Noxious Weed.

L. H. SCUDDER, 63-143.

At the Northwestern Convention at Chicago, last fall, it was stated that the laws of Illinois made it a penal offense to introduce or plant melilot or sweet clover, and after some discussion in regard to the matter, Mr. M. M. Baldrige and myself were appointed a committee to investigate, and if we found any such laws in existence to try and secure the repeal of the same during the present session of our legislature.

I do not understand that any formal report was required of us, certainly not until the next meeting of the Society, therefore I will report what action I have taken in the matter, and will ask Mr. Baldrige to give us, through the BEE JOURNAL, the results of his investigation.

I have examined the statutes of Illinois carefully and cannot find the name mentioned. There are only two plants named, viz.: Canada thistles and castor beans, which, by the laws of Illinois, are declared "noxious weeds." It is true that the law seems to imply that there are other noxious weeds and fixes the same penalty for introducing as those above named. It is evident that the burden of proof

would rest on the complainant, and if he failed to establish the fact of the noxious character of the plant, the case would fail. Therefore, I conclude that if sweet clover is as valuable as we believe it to be, we should have no hesitancy in giving it a fair trial. I have not been able to find any conclusive evidence to convince any one that the introduction of sweet clover could be objected to by any reasonably disposed person.

The Farmers' Practical Encyclopedia speaks of it as a good honey plant, but "spreading as a persistent weed." If that is the worst that can be said of it, let us raise as much of it as we see fit, trusting that the good will overbalance the evil, enough to make all feel friendly towards it.

New Boston, Ill.

For the American Bee Journal.

Comb Honey Rack.

JOHN T. SMITH.

I send to the BEE JOURNAL a sample of my improved honey rack for holding the 4¼x4¼ sections. I send two racks; they cover one hive; one full of sections in place, and one, empty. 1. I can use one rack at a time on light colonies or box hives; 2. I can tier up, one upon another, on strong colonies, without adding more than one at a time; 3. By having each tier ¼ inch apart I can get the honey off as fast as it is finished, as I can work in between the other tiers; 4. By taking off honey as fast as finished the combs are nice and white, the bees keep at work all the summer, and do not get the rack completed, but have partly finished ones to keep them encouraged; 5. The shape of the rack is such that the bees cannot glue the sections fast or soil the same; 6. By being ½ inch inset for sections to set in the rack, separators can be used resting on the top edge of the rack, leaving ⅜ inch space below the separators, for bees to pass through; 7. By using the rubber cord to hold the sections in place it holds all tight in dry weather or damp, and the cord is not in the way when tiering up; 8. I can take the sections out of the rack and turn one of the racks upside down on the top of the hive, for winter use, that forms the best of winter passage over the top of the frames. I like it as well as "Hill's Device" for that purpose; 9. In taking out and replacing sections, the bearing is so small that I do not kill as many bees as with other racks, where the bearing comes on the entire bottom of the section. In tiering up I do not raise the rack, but raise one tier, 6 sections, at a time; putting the empty ones at the bottom, and partly filled ones on top.

I have 83 colonies of bees in winter quarters; part of them are packed in chaff, on the summer stands, and part are in the cellar. I used the rack on them last summer with the best of satisfaction, as have all the bee-keepers in this vicinity.

Bellevue, Mich.

[The rack is placed in the Museum for the inspection of visitors.—ED.]

For the American Bee Journal.

Northeastern Michigan Convention.

In pursuance to a call, the beekeepers of Northeastern Michigan met at Flint, Tuesday, Feb. 13, and organized what will henceforth be known as "The Northeastern Michigan Bee-Keepers' Association." A constitution and by-laws was adopted, and the following officers elected: President, R. L. Taylor, Lapeer; Vice-President, Dr. L. C. Whiting, East Saginaw; Secretary, W. Z. Hutchinson, Rogersville; Treasurer, Byron Walker, Capac. The next annual meeting is to be held on the first Wednesday in March, 1884, in Lapeer.

After the election of officers, the appointing of a committee on exhibits, and the decision as to the place of next meeting had been arrived at, and the president and secretary had been instructed to call a special meeting just before the meeting of the State Association next December, the convention adjourned until 1:30 p. m.

At 1:30 the meeting was called to order by President Taylor. The first subject for discussion was that old, but ever interesting one, of

Wintering Bees.

Dr. L. C. Whiting: I would have a good colony; a good queen, good brood, and an even temperature.

Dr. Rulison: I would feed plenty of granulated sugar, and winter in the cellar. Would have the cellar well ventilated and dry; the temperature between 32° and 35°, and keep no vegetables in it.

Prof. Cook: Why would you have the cellar dry?

Dr. Rulison: Because the water at one time leaked into my cellar. Where the water came in, a colony died, and the combs were very moldy; at the dry end of the cellar the bees wintered best.

Prof. Cook: I have wintered bees five years successfully in a cellar, in which the water stood one foot deep, what do you think of that?

W. Z. Hutchinson: Within the last few days I have had the pleasure of visiting Mr. J. H. Robertson of Pewamie. He has 350 colonies in an out-of-doors cellar. There is a spring in the cellar, but, when I was there, the water had not yet commenced to flow, and Mr. R. was shoveling snow into the cellar by the bushels. The snow gradually melted, and the atmosphere was so damp that it could be almost felt. The bees were in splendid condition. I have no hesitation in saying that they were the finest lot of bees that I have seen this winter.

Clark Simpson: Poor honey often causes dysentery. Bee-keepers often make a mistake in extracting their early-stored, well-ripened honey, and letting the bees fill their combs with fall honey, which is often of poor

quality. I think the walls of chaff hives are usually made too thick.

Byron Walker: I would like the experience of Mr. Simpson that induced him to think that chaff hives should have thinner walls.

Clark Simpson: When the walls are thinner, the bees receive the benefit of the sun's warmth.

Dr. L. C. Whiting: One winter I had hives facing in different directions. The only ones that survived the winter were those with their entrances facing towards the south. Probably the sun kept the entrances thawed open.

Dr. Rulison: I have known bees to winter well, buried deeply in snow.

J. L. Wilcox: I have kept bees 25 years; I fasten them in the hives during the winter, and have never lost many colonies.

Byron Walker: I think the protection that bees have, may have something to do with whether they can be fastened in without harm. When bees were heavily covered with chaff, and they became uneasy, I have removed the chaff, and the bees soon quieted down. The kind of winter stores that the bees have, has much to do with how they winter.

T. C. Pollock: I do not advise shutting bees into their hives. I leave a space above the bees in the cap. My bees winter best in the dampest part of my cellar. I would not advise beekeepers to take away the best honey and compel the bees to winter on late gathered honey, that may be of poor quality.

L. E. Welch: I consider it of the greatest importance that the bees should be kept in an even temperature.

Prof. Cook: I agree with Mr. Welch, but there are many other things besides temperature that must receive attention. I once poured water over every opening in the hive. This was during freezing weather, and the bees were completely frozen in, or sealed up with the ice. Snow was then shoveled over the hives. The bees came through all right, but I would not advise such methods.

L. E. Welch: Although I consider an even temperature of great importance, yet I will admit that good food is also important.

Prof. Cook: I have visited the bee cellars of D. A. Jones, of Beeton, Canada. The walls are 3 or 4 feet thick, being filled with sawdust. Each cellar is supplied with air through 8-inch tile that are laid beneath the frost line, and reach the open air at a distance of 200 feet from the cellar. The cellars are ventilated at the top. There is also an ice-box over each cellar; by putting ice into these the temperature can be controlled during the warm spring days. I would not carry bees out during the winter, unless they become uneasy, and were soiling their hives.

R. L. Taylor: Bees sometimes become uneasy, and then quiet down again without being carried out of the cellar.

L. E. Welch: Perhaps they move about, cluster in a new place, and begin to feed upon a better quality of honey, and hence they quiet down.

Byron Walker: I have tried sub-earth ventilation, but it failed unless the bees were furnished with proper food. I do not think the late gathered honey is always of the best quality.

Prof. Cook: Late gathered honey may not always be natural honey; it may be the product of plant lice.

W. Z. Hutchinson: I have 11 colonies out of doors. Some of them are now dead from dysentery, and I think they will all die except one, which is in good condition. This fortunate colony had all of its honey extracted last fall, and was fed granulated sugar.

Clark Simpson: I would not put more than 50 colonies in one cellar. I would have the cellar frost proof, and well ventilated. Would be sure that the bees had good food, and that the hives were so arranged that they would not be jarred.

Dr. L. C. Whiting: If my bees needed feeding, I would feed them honey that I have put away for that purpose.

Prof. Cook: Yes, doctor, but if we had no honey laid away, then what should we feed?

Geo. W. Hand: I would feed the best white sugar. I have taken bees that my neighbor was going to brimstone, fed them upon white sugar, and carried them through all right.

Dr. Whiting: I can shake the bees off the combs in the fall, extract and sell the honey, go visiting during the winter, buy bees in the spring, and make more money than you can by wintering your bees.

W. Z. Hutchinson: And I can scrape up the bees that you shake off, feed them sugar, sell them back to you in the spring, and have more money left than you will.

Clark Simpson: I knew of a man who wintered a colony of bees without combs, by feeding them sugar, and occasionally rye flour. The bees filled their hives with combs during the winter.

Can the production of honey be overdone?

Dr. Rulison: I sell my honey in my home market—have educated the people to eat it. If the people are only educated to eat honey, they will eat all that we can produce.

M. D. York: I will sell my honey in my home market. Many people eat honey now who never thought of eating it until it was produced in their neighborhood, and their attention was called to the matter.

Dr. Rulison: As long as there are so many losses during the winter, there will be but little danger of the business being overdone.

Dr. Whiting: Now that the markets of the Old World are opened up to us, we can sell all of the honey that we can produce, and that, too, at good prices. If we send the Europeans nothing but good, pure honey.

Prof. Cook: C. F. Muth, of Cincinnati, who has had a very large experience in handling honey, says that we need have no fears of over production if we will only stop adulteration, so that the people will have confidence enough to buy the honey.

M. D. York: We have not labored entirely in vain; the people are be-

coming educated; just let me give an illustration: Last fall, to fill out an order, I was obliged to fill two jars with extracted honey that had just been melted up. A week or two afterwards, as I was in the store where the honey was on sale, the proprietor called me to one side and said: "You might just as well carry home those two jars of liquid honey; no one will buy them; people are beginning to find out that pure honey will granulate upon the approach of cool weather." I explained the circumstances to him, and the condemned honey was sold before I left the store.

The essentials of a good location.

Byron Walker: I would prefer a location in which the bees can find honey to gather as soon as it is warm enough for them to fly. Raspberries are excellent honey producers. Fall flowers are more certain to yield honey than those that blossom earlier. I would not advise any one to run away from white clover and basswood, but to take in the swamps and fall flowers, if possible.

L. C. Whiting: I would like a location that has willows, soft maples, barb maples, white clover, basswood; in fact, I want a succession of bloom.

M. D. York: I have sowed alsike to help furnish a succession of bloom, but the honey is of poor quality compared to white clover or basswood.

Prof. Cook: It seems to me, Mr. York, that you must be mistaken; are you certain that it was alsike clover honey that you found of poor quality?

M. D. York: Yes, I am certain. The bees were working upon nothing else; and I extracted it before they commenced to work on anything else.

W. Z. Hutchinson: I, one year, had 300 pounds of alsike clover honey, and nothing could be finer. It has a pinkish color, while the flavor, although distinct, is very pleasant.

Prof. Cook: Instead of moving to a location near swamps, would it not be better to cultivate honey producing plants? Some have reported obtaining excellent results by cutting alsike clover just before it blossoms, thus bringing it into bloom after the close of the basswood honey harvest.

D. Shangle: I have sowed alsike clover with wheat. It made such a growth that, when the wheat was cut, the clover also was cut. The clover grew up again, blossomed and produced honey.

W. Z. Hutchinson: Mr. J. H. Robertson advises pasturing alsike until the last of June. By this method he says that two crops can be obtained; one crop of honey and one of seed.

Comb Foundation.

Prof. Cook: I have used foundation ever since it was first sent out by "John Long," or whoever he was, and I am becoming more and more convinced, each year, that it is one of the greatest inventions that has ever been given to bee-keepers; I do not think, however, that drone foundation is going to be used.

R. L. Taylor: I consider foundation invaluable. One of its greatest advantages is that it enables us to con-

trol the production of drones. I have used the flat-bottomed foundation in boxes, and with this I have found a "fish bone" in the honey. By filling the boxes with foundation, the bees build their comb straighter and quicker. I have given the bees a frame of foundation, late in the afternoon, and the next day found it drawn out and filled with eggs. I have used all kinds of foundation, and, unless it is wired it will sag. In light colonies, or cool weather, it may work very well, but in full colonies, or hot weather, it will sag, warp or break down. If it sags, the top cells are drawn out so large that drones will be reared in them. With the Given press the foundation is made directly into wired frames, thus saving all trouble of fastening in the foundation.

J. H. Wellington: I have nothing to say against wired foundation or wired frames, but I do wish to say a word in favor of the flat-bottomed foundation. I have used it very thin, and found no "fish bone" in the honey. Perhaps Mr. Taylor may have used thicker flat-bottomed foundation than I did.

L. C. Whiting: I wish to put in a word in favor of the flat-bottomed foundation. I have used the Given foundation, but the bees gnawed it out before the honey flow came. It may be because the Given was softer than the flat-bottomed.

W. Z. Hutchinson: May not the quality of the wax have something to do with this?

R. L. Taylor: So large a surface of the flat bottomed foundation receives pressure that it makes the foundation too hard, and instead of drawing out the wax the bees build on it.

J. H. Wellington: I have always noticed that the base of the cells were worked into a natural shape.

Dr. Rulison: I have used a great deal of foundation, and prefer that which is wired.

M. D. York: I use the regular Langstroth frame, and have kept the foundation from sagging by using what are called Cheshire rakes, but it is a very troublesome method.

D. Shangle: I use no wires, and have no trouble from sagging. My hives are 1 inch larger, each way, than the regular Langstroth.

Dr. Rulison: I live near Mr. Shangle, and I would say that he makes his foundation very heavy.

D. Shangle: I dip the boards three times. If the wax is very hot I sometimes dip once or twice more.

H. A. Fenner had used foundation 6 or 7 feet to the lb., and it did not sag.

L. C. Whiting: I have used foundation in which there was some paraffine, and it always stretched badly.

Prof. Cook: I have used the flat-bottomed foundation, and I must say that the bees did not work it out very readily.

Byron Walker: I would not have foundation for any purpose, made heavier than 6 or 7 feet to the pound.

Prof. Cook: I have seen them making foundation at Mr. Jones', and they reverse the dipping board each time they dip it, thus making the sheets of uniform thickness.

R. L. Taylor: There is a great difference in wire; some is "springy" and will tangle up, other kinds give no trouble; get that, that does not "tangle." I wind the wire around a board, and the board is of such a length that when the wire is cut where it passes around one end of the board, the pieces of wire are just the right length for wiring a frame.

Mr. Taylor then had his Given press brought into the room. A dish of water was brought to him. He put one or two pieces of concentrated lye, as large as a kernel of corn, upon the dies, wet an old shoe brush in the water, and with it washed the lye all over the dies. Some wired frames were piled beside the press, the small bundle of sheets of wax that had been lying behind the stove were handed to Mr. Taylor, when presto, the wired frames filled with the beautiful foundation were soon being passed about the room amid the clapping of hands and exclamations of delight. A hearty vote of thanks was extended to Mr. Taylor for bringing the press and showing the manner in which it worked.

Mr. Shangle had an Olm foundation machine on exhibition, and wished to show how it worked, but had not the proper lubricator there.

Overstocking.

Prof. Cook: I think it well-nigh impossible to overstock a locality. If there is plenty of honey it is difficult to have bees enough to gather all of it; if no honey is secreted, it makes little difference whether there are few bees or many.

Clark Simpson: The secretion of honey is so rapid that I consider it impossible to overstock a locality.

Byron Walker: I have noticed that, wherever a few colonies of bees are kept just out of my range, they always give better results than I get from my large apiary.

J. H. Wellington: There was, at one time, 600 colonies kept in the city of Saginaw, and my partner (Mr. O. J. Hetherington) and myself were obliged to move most of our bees out into the country in order to get any surplus. We kept just enough bees at home to show that we were in the business.

Different varieties of bees.

Prof. Cook: I consider the Italians better than the blacks, and the Syrians better than the Italians. The Syrians are more prolific, and are excellent honey gatherers.

Clark Simpson: The Syrians are worse to swarm; but, for all of that, I like them.

Prof. Cook: It has been reported that they do not seal their honey properly. Did you notice anything of that kind?

Clark Simpson: Nothing of the kind, they make as nice comb honey as any bees.

M. D. York: I had a colony of Syrians, last season, that outstripped an Italian colony that was its equal in all respects that could be discerned.

D. Shangle: I have tried blacks, Italians and Syrians, and the blacks

made the most comb honey, excepting some hybrids that I have had.

Dr. Rulison: I would not take a swarm of blacks, and keep them black, if you would give them to me. Nothing suits me better than pure Italians. I do not want the Syrians, because they swarm so much, and because they are so cross. I do not like the black bees, because the moths trouble them so much, and because they are not of an even "temperament." Neither do I want imported stock; good, pure, home-bred Italians are good enough for me.

Byron Walker: I like the black bees because they do not swarm so much, and because they are the ones that pile up the comb honey ahead of anything else.

M. D. York: I have tried the blacks and Italians, side by side, for three years, and have discarded the blacks. I think that many discard the Italians because they do not understand them. The Italians and Syrians swarm more, simply because they are more prolific. I practice putting a swarm into a hive from which a swarm has issued a day or more previous; there is then spent that energy that a new swarm always has, in making comb honey in the boxes.

J. H. Wellington: Our hybrids beat everything in making comb.

The committee on exhibits reported as follows:

Mr. President, your committee on exhibits reports a very large exhibit. Our president, R. L. Taylor, of Lapeer, exhibits a Given press, wired frames, a Chapman press for piercing frames for wires, and comb foundation. Mr. Taylor, like all owners of the Given press, is very enthusiastic in its praise. He also showed how the press worked.

M. S. West, of Flint, shows crates, comb honey, extractor, hives with Langstroth frame, also one with Gallup frame, half-pound sections, and a plan of a bee house presented by his daughter.

J. H. Wellington, of Saginaw, presents hives with reversible frames, a Bingham smoker, and a Bingham and Hetherington honey knife. He values the reversible frame very highly. Reversing causes the bees to fasten the combs to the bottom bars, and sets the bees to carrying the honey, that is stored near the top bars, into the sections.

Mr. Clark Simpson, of Flushing, exhibits side-opening hive with arrangement for side-storing and chaff packing; a home-made, cold-blast smoker, combination seat and tool box, and a lamp nursery for hatching queens. In this combs are not put, but the queen-cells are cut out and placed in separate apartments. With no honey accessible, Mr. Simpson says that the young queens will not kill each other.

Rulison & Simpson, Flushing, exhibit fine samples of extracted honey.

D. Shaugle, Hazleton, shows the Olm foundation machine. He lubricates the rolls with thin flour starch.

L. E. Welch, Linden, shows a Simplicity hive with Gallup frame, crate filled with half-pound sections, and wood separators.

Byron Walker, Capac, presents one-piece sections, and combined storing and shipping crate. His sections have no recesses, but have, instead, projections on the ends. His section are 1 $\frac{3}{4}$ wide, and he uses no separator. His crate can be used at the side, top, or even in the middle of the brood nest.

August Koppen, Flint, exhibits a chaff hive with bottom board filled with chaff, and a large extractor with automatic arrangement for turning the combs.

W. Z. Hutchinson exhibits several neat pails of granulated honey, together with a stand for holding them while they are on sale in a store, a Bingham smoker, and a cold-blast smoker from Mr. Kemp, samples of all the bee papers, some bee books, and a photograph medley showing about 150 bee-keepers.

Dr. L. C. Whiting, East Saginaw, shows a Scoville smoker, a section crate, and brood section frame with only three sides, one side of which is sheet iron, which enables the operators to easily remove the sections.

A. J. Cook, L. C. Whiting, W. Z. Hutchinson, *Committee on Exhibits*.

Twenty-nine members were enrolled; the best of feelings prevailed, and, if the future meetings are as good as the one that has just passed, the Association will be a decided success.

W. Z. HUTCHINSON, Sec.

Eastern New York Convention.

The annual meeting of the Eastern New York Bee-Keepers' Association was called to order by President Tennant, at Albany, Jan. 2, at 2:30 p. m. The secretary being absent, T. Houck was appointed secretary *pro tem*. The minutes of the last meeting were read and approved. The president made a very appropriate and interesting address. Adjourned to 10 a. m.

President Tennant called the meeting to order at 10 a. m., and Secretary Quackenbush's report was read and accepted, and his bill was ordered paid. The treasurer's report was read and accepted; showing \$15.58 in the treasury.

An essay by G. W. House was read, the main points of which were as follows: "The Western bee-keepers labor for their united interests, by protection to their journals; by the advocacy of their fancied superiority of some work published, or the use of some implement manufactured in the West, and by a unity of action to keep us in the East disunited. Under the existing circumstances, I will venture to say that beyond the meeting and hand-shaking of friends, and the making of new acquaintances, conventions, as generally managed, are not beneficial to the specialist. I am now fully satisfied that publishing our minutes works positive injury to the Association and its members. It damages the society by driving therefrom our most eminent apiarists, who do not care to give to the world their discoveries and inventions, and then be abused and dictated to by novices. They would rather reserve what they know of value, and learn what they

can from the publication of our proceedings. The members of the society are injured because many penurious bee-keepers will remain at home, instead of giving you their attendance, and assist in sustaining the Association, knowing that they can read the proceedings at their leisure."

This essay called out considerable discussion. Mr. Vrooman favored publishing the proceedings; also that County Conventions send delegates to State Conventions; that many bee-keepers would not go so great a distance to attend a State Convention; that the delegate should be regularly elected at the County Convention, and delegate pay their own expenses.

Mr. Tennant thought the delegate should be instructed to the interest of the Association. He opposed all rings and monopolies. There are things on foot that are working injury to our interests. There are many bee-keepers who will not come, on account of their being henpecked and forced to tell all they know, to be published.

Mr. Wormer: The more knowledge one gets of bee-keeping, the more he wants to go into the business. He thinks there is sufficient demand for all the honey we can procure, and that if we cannot publish anything, we certainly cannot learn anything.

Mr. Markell believes in making true reports and giving it to the public.

Mr. Garret said bee-keepers are like boys that hate to be outdone by others—and make their estimates too high, so as to be up with their neighbors.

Mr. Robdell thinks a great deal of our knowledge should not be published; high estimates are an injury.

Mr. Wright: The proper way to make our reports is by number, as Western men do.

Mr. Denton thought we ought to advance new ideas to each other; he is in favor of having conventions; what is practical with one, is not with another; an experimental knowledge is the best.

Mr. Haverly: Best posted bee-keepers should tell what they know, for the benefit of inexperienced ones.

Mr. Tennant: We ought to have a system to protect ourselves; bee-keeping is increasing to such an extent that we should be protected by organizations, County and State; we must have protection by legislation, if necessary. There are no kinds of business but have an organization, to set prices. Many bee-keepers are too penurious to attend the conventions—thinking they can get it all out of the bee journals. If they cannot come and take part in the convention, they are not worthy to be called "Brother Apiarist."

Secretary Houck said he had gained his knowledge of bee-keeping by first reading "Quinby's Bee-Keeping," and taking the various bee journals, with his own experience, and he believed that they all had gained most of their knowledge in the same way, and is it for us to say that it must stop there? Suppose Langstroth and Quinby had been so selfish and not made their experiments and practical experience public, where would apiculture stand to-day? That the bee

journals have done more to work up the demand of our products than anything else. Because we have gained that knowledge, shall nobody else have the chance? He offered the following: *Resolved*, That we publish the proceedings of this convention in full. Carried.

After a lively discussion Mr. Garret offered a motion to rescind the resolution, which was carried, and the question was laid on the table until to-morrow.

The convention was called to order at 1 p. m. President Tennant being absent Vice-President Vrooman took the chair. The election of officers resulted thus: President, Sol. Vrooman; Vice-President, A. Snyder; Secretary, T. Houck; Treasurer, H. W. Garret. The secretary read an article by A. J. King, of New York.

[For this essay see page 22.—Ed.]

After a lively discussion the convention adjourned until 7 p. m.

Meeting called to order at 7 p. m., President Vrooman presiding. The following questions for discussion were reported by the committee:

1. "What is the Best Method of Starting Nuclei for Queen-Rearing?"
2. "How Long will a Queen Remain Profitably Prolific?"
3. "What Improvements can we Make in Marketing our Products?"
4. "Shall our National Convention be Held Outside of the United States?"

The first and second questions were discussed in their respective order.

Mr. Adams makes about four nuclei out of one of his strongest colonies. His hives hold eight frames, thus taking two frames of hatching brood for each nuclei.

Mr. Tennant: It depends on the season. Considers young bees the best for queen-rearing. He breeds only from his strongest colonies—those that winter and make box-honey best. Considers two frames of hatching brood the best for nuclei.

Mr. Boomhower: Took about 18 colonies and made one nuclei from each. He took the box he used to the hive, found the queen and took a frame of brood—one that has the brood near the centre of the frame—put it in his box, first brushing the bees off of two frames into the box, and in 4 or 5 days he would do the same thing, and so on until he had made about 90, and he has had an original colony swarm the same year.

Mr. Adams: My experience with a lamp nursery was very unsatisfactory.

Mr. Tennant thought it depended somewhat on how the queen was reared. Preferred one reared under the swarming impulse, and in the forepart of the season. He thought about three years was the extent the queen was profitably prolific, but sometimes longer.

Secretary Houck: You could force a queen to lay in two years what would under other circumstances take four. Adjourned to 9 a. m.

Convention called to order at 10 a. m. President Vrooman in the chair.

This session was opened by a lively discussion on an editorial article in the BEE JOURNAL of Dec. 20, 1882, page 802, on "Half-Pound and Penny

Packages, or Packages of the Future." The members thought that it was very important that the convention complete the idea of protection, discussed yesterday. They wanted to see the convention placed upon such a foundation that it would have an influence at home and abroad. That Mr. Newman, editor of the BEE JOURNAL, should be censured for his officiousness in writing, and going about with Mr. Ripley, doing all he could against the interests of those to whom he looks for support. If Mr. Newman cannot stand by the producers they should withdraw their patronage. That the producers must pay him for everything he does in the way of printing, etc., and at the same time he was pushing himself against their interests. And also, as a convention, they should ask that Mr. Newman retract and reconsider the article in question.

Motion made by Mr. Tennant, and carried unanimously, that the convention resolve itself into a committee of the whole and adopt the following:

Resolved, That we ask Mr. Newman, editor of the BEE JOURNAL, to reconsider the article as printed in the Weekly BEE JOURNAL of Dec. 20, 1882, on page 802, on "Half-Pound Sections, or Penny Packages, or Packages of the Future," together with what he himself has said in the article, and the influence that he has set forth in confirmation with that of Mr. Ripley, agent of the firm known as Crocker & Blake, of Boston, and see if the items referred to inure to the best interests of the producer; also we ask Mr. Newman if he does not consider it officious to publish or recommend it to the public, to the injury of the producer.

[For reply to the above, see first page of this paper.—Ed.]

A lively discussion followed in regard to the proper size of box.

Mr. Tennant favored the 2-lb. boxes. That we should not deviate from 1 to 2 inches thick, as it makes the neatest-looking card of honey; it also was the most natural for the bees to work.

Mr. Vrooman prefers one $5\frac{1}{4} \times 5\frac{1}{4} \times 1\frac{3}{4}$ thick.

Mr. Van Dusen thinks it is a benefit for both the supply dealer and producer to have one standard box, then the supply dealer could in the winter time make up a large stock and be ready to furnish his customers without that delay which sometimes causes so much trouble.

Mr. Garret was of the opinion that the 2-inch was the most used of any, and that the bees would fill a 2 inch box quicker than one that is only $1\frac{3}{4}$ thick.

Secretary Houck said the majority they manufactured were 1 15-16 thick, called the prize box; and thought it was about the right size, and could be made easier, for the reason that 2-inch plank, as a general thing, would plane only 1 15-16; if they had to be 2 inch they would have to block up the lumber.

Mr. Boomhower said that those manufactured by Mr. Manum were 2-inch excepting the $4\frac{1}{4} \times 4\frac{1}{4}$ dove-tailed,

and those were $1\frac{3}{8}$ thick; he preferred the $1\frac{3}{8}$ box.

Secretary Houck offered the following, which was adopted: *Resolved*, That we adopt as a standard the 2-lb., and nothing smaller than the $5 \times 5\frac{1}{4} \times 2$ inch section.

Motion was made and adopted that we add the following to "article two" of the constitution: "However we invite exhibition of products and supplies, and time will be given between sessions and at proper times appointed for examination."

Another motion was made and adopted that the secretary invite exhibition of all apianian supplies at the time of his giving notice of meetings.

Where shall we hold our next annual convention came under discussion. Finally, it was voted to be held at Albany, in Agricultural Hall. Not knowing when we could have the hall, it was left to the president and secretary; but they were to get it as early in January as possible.

Adjourned until 1 p. m.

Convention was called to order by President Vrooman at 1 p. m.

The president, upon motion, appointed the following members as a committee on questions for discussion at our next annual convention. Questions to be reported to the secretary on or before Dec. 1, 1883: W. L. Tennant, Schoharie, N. Y.; A. Snyder, Clarksville, N. Y.; G. H. Adams, North Nassau, N. Y.

Motion made and adopted, that we have a programme, that it contain three essays, that it also contain the motions solicited by the question committee; and that all be reported to the secretary, by the respective committees, by Dec. 1, 1883, and that the secretary have the same printed and circulated to each member of the Association, and to such other members of sister associations as the president and secretary shall direct.

Secretary Houck then read a paper written by James Heddon, on dysentery, or bee cholera and spring dwindling. Of the latter he said: "I believe that no colony that was healthy when the days of long periods of confinement ceased (which we call winter) and the days of oft-repeated flights arrived (which we call spring), ever 'spring dwindled.' Spring dwindling is loss of bees in daily flights, from weakness engendered by a disease of the intestines, called dysentery, which had not, at the time of flight, progressed far enough to make any outside show, but was all held within the body of the bees, hence was unobserved by the apiarist. It is dysentery in disguise."

Mr. Tennant thinks a cleansing flight will sometimes cure dysentery, if they have not been confined too long; old bees are more liable to have the dysentery than young bees—making it quite necessary to go into winter quarters with a good supply of young bees; he does not believe that pollen alone is the cause of dysentery, but eating it in connection with honey, and continual cold weather without purifying flights.

Mr. Vrooman had lost over 100 colonies in one spring, with dysentery;

but did not believe pollen alone was the cause.

Resolutions of thanks to the three writers of essays, and the late president and secretary, were passed.

Shall the National Convention be held outside of the United States, was discussed. Many members held it was a North American convention, instead of National, and, therefore, could properly be held in Canada.

There was considerable interest shown in the discussion of what improvement can we make in marketing our products.

Mr. Vrooman thinks we ought to hold on longer, and not be in so big a hurry to dispose of our crop; that October is about the right time to ship honey; he would not send it off on commission, but sell it right out, and get the money in his pocket.

The members were of the general opinion that the best way was to let buyers come and offer, instead of running after them; also that we were apt to be in too much of a hurry to sell our honey.

Exhibiting honey and apiarian implements at the State Fair, was discussed, and the following resolution was carried: That the president and secretary confer with the managers of the State Fair, for a suitable place and room for the exhibition of honey and implements for the apiarists of the State, and also offer premiums for the same.

Secretary reported \$12.50 fees received, of old and new members.

The question in regard to the publication of the proceedings came up again. After considerable discussion it was decided to leave it to the discretion of the secretary, what part to publish and what not.

At the last moment there was a resolution adopted that we glass all our boxes, both large and small, before sending to market.

Convention adjourned to meet again in one year. THEO. HOYT, Sec.

Maine State Convention.

The fourth annual meeting of the Maine Bee-Keepers' Association was held at Dexter, Feb. 8, 9, 1883.

President Addition gave his annual address at the commencement of the afternoon session. He succinctly stated the objects of the Association and the progress it had made. He briefly reviewed the progress bee-keeping had made during the last few years in other parts of the country, and the spirit of enthusiasm having been felt here in the Eastern States, bee-keepers were waking up and taking hold of the business in earnest.

The report of Secretary Hoyt was in substance as follows: The Maine Bee-Keepers' Association numbers 52 members—42 male and 10 females, showing a gain during the year of 31. Meetings are held quarterly. 36 members report as follows: Number of colonies of bees Oct. 1, 1881, 772; number May 1, 1882, 437; showing a loss during the winter of 281 colonies. Number of colonies owned Oct. 1, 1882, 709; of this number 391 were

black bees, and 318 either Italian, Cyprian or hybrids. Number of colonies sold during the year, 119; number bought, 106; number of queens sold, 175; number bought, 73; pounds of honey taken, 5,437; pounds of wax, 335. Average amount of honey from each colony owned May 1, 1882, 12½ pounds. The average for the year before was 36 pounds.

97 bee-keepers, not members of the Association, had reported, giving the following results: Number of colonies owned Oct. 1, 1881, 1,092; number May 1, 1882, 863; number Oct. 1, 1882, 1,215; 739 of these were black; 476 were either Italians, Cyprians or hybrids. Number of colonies sold during the year, 161; number bought, 118. Number of queens sold during the year, 133; number of queens bought, 61. Pounds of honey taken, 16,003; pounds of wax, 459. Total number of colonies Oct. 1, 1881, 1814; number May 1, 1882, 1,300; number Oct. 1, 1882, 1,924. Of these 1,120 were black bees, and 694 either Italians, Cyprians or hybrids. 283 colonies were sold during the year, and 224 bought. Queens sold, 308; bought, 134. 21,440 pounds of honey were produced, and 790 pounds of wax.

Of hives used 31 were the Langstroth frame, 17 the Colton and other styles, 8 were the Gallup frame, and 8 the Quimby frame. 6 had the Torrey and Maine standard hive, and 5 the shingle (Eureka) hive. Several other kinds were used by a few.

In wintering, 42 adopted placing the hive in the cellar; 40 winter on summer stands, and use packing in chaff, straw, sawdust, boughs, etc. A few winter bees in chambers, unoccupied houses or bee-houses built for the purpose.

The subject of feeding bees was introduced by a paper from Mr. Lucien French. His main points were, that feeding was essential both fall and spring, the latter time with all colonies, the former to weak colonies, so as to give them sufficient store for winter. The best feed was the purest sugar we could get. Never feed glucose. He had tried it, and it cost him dearly. Believed he was out \$100 in consequence of the experiment. The best place to feed was inside the hive. To feed outside incited to robbing. To feed for brood-rearing, give a small quantity each day. If feeding for stores give it to them as fast as they would carry it away. A candy made of half a pint of water to four pounds of sugar melted and turned into shallow tins and laid upon the bars, was a good way to feed in winter.

Considerable discussion upon the feeding question followed the reading of Mr. French's paper. The points were that very much of the granulated sugar in market was adulterated with grape sugar. That in some cases bees would not always be incited to fighting by out-door feeding. The coffee A sugar was preferable as a feed for bees, especially in spring. Glucose or grape sugar was injurious to bees, and under no circumstances should it be fed to them.

To make bee-keeping profitable, was the basis of an essay by Mr.

Hutchins. He thought our bees might possibly be superseded by some newer sort, but did not think that kind had been found yet. In wintering bees experience seems to prove that the hives packed in chaff were preferable to wintering in the cellar. The spring dwindling, that universal complaint, was due in great measure to wintering in warm cellars. Use frame hives, and examine the bees in the spring to know their condition. Cannot do it with the old box-hive. In dividing, do it so as to have each colony as strong as possible in as short time as may be. To keep bees profitably one must love the business, and make pets of his bees. Take and read some good journal devoted to bees. Keep up with the times, there is much to be learned yet. Keep a record of all the colonies and queens, and their qualifications and attainments. Have everything in readiness at the proper time, and never put off doing things which ought to be attended to immediately.

The question of wintering bees was discussed with a pretty strong leaning to out-door packing in some way. Those that had tried chaff packing had found it satisfactory. Some adhered to cellar packing.

SECOND DAY.

The election of officers resulted as follows: Mr. F. O. Addition, of Dexter, President; Wm. Hoyt, Ripley, Secretary; J. W. Hodgkins, Dexter, Treasurer.

Vice-presidents from the several counties were elected as follows: Aroostook, H. B. Chapman; Androscoggin, L. F. Abbott, Lewiston; Hancock, L. S. Brewster, Dennysville; Kennebec, H. B. Coney, Augusta; Penobscot, J. W. Hodgkins, Dexter; Piscataquis, W. A. Cotton; Waldo, J. W. Linekin; Somerset, S. W. Crockett.

A. B. Coney, Isaac Hutchins and Wm. Hoyt were appointed a committee to confer with the State Agricultural Society's officials, regarding future exhibits of honey and bee implements at the State Fair.

Mr. Isaac F. Plummer, of Augusta, gave his views and experience in providing pasturage for bees by sowing some special crop for that purpose. His experience had not been great, but he had tried it enough to know that to a certain extent it would pay to plant or sow for bees. Fruit-culture and bee-keeping, he thought, should go hand in hand, for fruit trees in bloom were a source of honey. In extending our orchards we extended the facilities for our bees to gather honey. Every farm has more or less waste land which might be appropriated to raising some plants for the bees. Where sweet clover will grow it is one of the best honey-producing plants we have. Another honey producing plant which blooms from July to October is borage. It is an attractive flower for field or garden. It needs a dry, rich soil in order to thrive. He sowed some last year, and it did finely. The bees worked upon it constantly. He liked the plant so well that he will sow more another season. Other plants with which he had had some experience as

honey-producing plants were catnip, motherwort, boneset, figwort, spider plant, mignonette, Chinese mustard, clover, golden honey plant, etc. He thought if more attention was paid to this branch of bee-keeping it would be made to pay better, and he would advise all to plant largely of honey-producing plants, as he believed it would pay in the end.

In discussing this subject, the conclusions were that of the honey plants, sweet clover (mellilot) was as good as recommended, and one of the best to sow for bees. Dutch clover or white honeysuckle was our best natural plant. Borage, by those who had tried it, was liked for its honey-producing properties. Basswood, in localities where it grew extensively, yielded much and a good quality of honey.

The question whether bees would work upon red clover to any great extent was discussed, the conclusion being that if other flowers were blooming in abundance red clover would be slighted, but where honey was short and red clover blossoms abundant, honey bees would visit it. Mr. Reynolds, of Clinton, had often observed black bees on red clover, but no Italians. Mr. Hoyt had seen the last named busily engaged upon it.

Mr. Addition said we should use great care in introducing new honey plants, not to spread noxious weeds upon the farm.

The question was asked if it would be judicious to discard the German black bees in favor of the Italians?

None were so fully confirmed in their convictions regarding the newer races as to risk their success entirely upon them. Many favorable opinions were expressed of the Italian, Cyprian and others—pure and hybrid.

In stopping absconding swarms Mr. Hodgkins related a method which he found successful. He affixed an oblong piece of cloth to a pole and struck this amongst the bees as they circled away towards the woods. Always strike in the centre of the circle of bees, for the queen would be there, and if she was demoralized in her flight the bees would alight.

The committees appointed to examine the various hives and implements on exhibit, made their reports at the opening of the afternoon session. Three patterns of hives were shown; the Quinby closed end frame, Simplicity with Langstroth frame and the Eureka, carrying the Gallup frame. The committee gave the preference to the Eureka made by Mr. Addition. On feeders, of which there were a number shown, the first preference was given to those exhibited by Mr. Hoyt and Lucian French, the two being very nearly alike. Queen cage, to S. M. Crocker and Wm. Hoyt, extractor; 1st "Novice," shown by Mr. Hoyt; foundation machine, 1st to Lucian French; foundation, H. B. Chapman, 1st; L. French, 2nd; wax, Wm. Hoyt; transferring tools, L. French; and same on wired frame; foundation fastener, Wm. Hoyt; tongue register, Wm. Hoyt; entrance contractor, E. P. Churchill, North Auburn.

Secretary Hoyt had experience in rearing three or four different races of bees, called attention to the coming bee. In the first place, to determine the kind we will keep, we should consider the object to be attained. Some keep bees for pleasure, but most of us for the profit they bring. Now, the bees that will gather the most honey, are the ones that will give the most profit. How shall we attain the desired result? By a judicious crossing of different strains and races, and selecting those which give the best results. Colonies vary greatly in the honey-gathering capacity. Those that are the best should be noted, and from these rear the bees we keep. From what statistics he had gathered, thought the average of honey throughout the State, was not over 25 pounds to the colony. Was this satisfactory? After four years experience with yellow bees, was satisfied they were superior to the blacks. As to the different races of bees, he thought the Italians very industrious, amiable and beautiful, and better honey-gatherers than the blacks. From his experience thought the Cyprians the best honey-gatherers known. They were very prolific, and the most beautiful bee with which he was acquainted. As to their disposition it was not always to be depended upon for amiability. The Syrian bees he had had limited experience with. It was claimed that they were very prolific and good-natured as the Italians. The coming bee must possess the energy and hardihood of the Cyprians, the docility of the Italians, with the prolific qualities of the Syrian bee. He was not prepared to point out any particular course for bee-keepers to pursue, but we should not be content with 25 pounds of honey from a colony, when some of the best give 100 pounds or more. One advantage of old-time keeping over the present was the "survival of the fittest," as bees that did not gather sufficient store to winter, died off or were consigned to a brimstone place. Now, colonies short of stores are fed, and every queen kept alive if possible, whether they possess any good qualities or not. A queen should not be tolerated unless her progeny are possessed of the following qualities: Good honey-gathering; hardy to winter; easy to handle; yellow bands. Do not be satisfied with anything short of these, and thus hasten the arrival of the coming bee.

The subject of re-enforcing colonies, by a queen reserve system, was presented by L. F. Abbott, agricultural editor of the *Lewiston Journal*, entitled, "Pointing to a Practical Point." He began by saying that the first requisite to success in any business was to become acquainted with the fundamental principles upon which the business was based. To rightly understand bee-keeping was to become familiar with the nature and instincts of the bee. Much study by comparatively a few individuals during the past few years had brought to light many mysteries of the bee hive. The point of practical importance he desired to offer for consideration was that of providing reserve laying

queens to be used at swarming time to provide re-enforcements for both the old colonies and swarms under certain contingencies. When bees are allowed to swarm naturally, much time is lost between the exit of the old queen and the time when the hive will feel the benefit of the progeny of the young queen; often amounting to two or three weeks. As the old queen goes out with the first swarm, matters at the old home are left in a sort of transition state; the women folks all stirred up and the boys fast leaving home. Some little fellows are continually emerging from the cells, the progeny of the old queen, but they, by the 21st day after the old queen turns her back on them, are all about house. In the meantime another swarm has gone out with a young, giddy and inexperienced queen, who remains with her family, but unable to perform proper duties for a number of days. This occurs at the season when honey is most abundant. Time is honey, and honey is money. What means shall we adopt to re-enforce these hives and bridge over this delay while these young housekeepers are getting ready to settle down to the real business of life? The remedy seems to be to partially adopt the system of artificial swarming in so far at least as to provide reserve queens, which, becoming fertile, will be in readiness to step into the old hive on the exit of the old queen, and also when her daughter leaves, and go immediately about the business of laying eggs. By their exchange the supply of reserve queens would be kept good, and non-laying queens be replaced immediately by fertile ones.

Mr. Hoyt, in reply to a question, remarked that the extractor could be profitably used in Maine. He believed it one of the most useful inventions of the age. He believed we could obtain much more honey by its use than in swarming for box honey. Should practice artificial swarming, if the extractor was used, as we could keep colonies more equalized in that way. Would extract as fast as the honey came in, and if colonies were short in the fall, feed for winter.

After some discussion, relative to the matter of place for holding the next meeting, it was left discretionary with the president and secretary.

Central Illinois Convention.

A convention was held in Bloomington, Ill., on Feb. 13, to organize a Society. Mr. J. L. Wolcott stated the object, and a committee was appointed to present a constitution and by-laws. 32 persons signed the roll.

The committee on constitution presented its report, which was adopted. The Association is known as "The Bee-Keepers' Association of Central Illinois."

The officers constitute a committee to select subjects for discussion, and to appoint members to deliver addresses and read essays. Meetings are held once in three months.

J. L. Wolcott was chosen permanent president and James Poindexter,

secretary. Mr. Wolcott spoke briefly of the importance which bee-keeping had assumed, especially in Central Illinois. He thought such an association was a necessity, and believed its work would be advantageous to all concerned.

Mrs. F. A. Baller was chosen vice-president, and O. Barnard, treasurer.

The next regular meeting will be held on the second Wednesday of May next, at 10 o'clock a. m., an appropriate date, as at that season the bees will have swarmed, and topics of interest can be presented. The Association will meet at Surveyor Ela's office until further notice.

JAS. POINDEXTER, Sec.

SELECTIONS FROM OUR LETTER BOX

Bees in Cellar Doing Well.

In April I bought 5 colonies, increased to 11 by division, caught a runaway swarm and took 658 lbs. of extracted honey. Thanks to Cook's Manual and the BEE JOURNAL. Bees are in cellar, which is ventilated, as Prof. Cook recommended, and, so far as I can tell, are doing well. In the above report I should have used *we* (that would include my wife and little girl) instead of *I*, for I have not walked without the use of crutches for over 15 months. J. R. CRAIG.

Beatrice, Neb., Feb. 27, 1883.

Large Yields of Honey in Texas.

Several years ago I became acquainted with the AMERICAN BEE JOURNAL, and have profited much from its able writers, and now I look with delight for its more than welcome weekly visits, and it is not only necessary to have an able editor at its head, but it must be supported. The grand watch word is: "Keep all colonies strong;" yes, pile on your subscriptions by the thousands, and still there is room for more, and the JOURNAL grows. Does he split up this colony into 3, 5, or even 10, and make a little puny sheet out of each? No; if needs be he moves to a larger hive, where he can find more room, pile on story after story until the great BEE JOURNAL hive is filled full every week. Just so, when I take the editor's advice to keep colonies strong, by adding story after story, not by doubling up two or more colonies, but by simply giving the one colony plenty of room as it increases, thus preventing any division by natural swarming, whereby I am enabled to get 300, 500 or 800 lbs. of extracted honey from single colonies, the cry is "such reports may be true in fact, but totally unfair, and therefore unreasonable." I cannot see the unreasonableness of such reports. Do not the authors of these reports tell how they accomplish these grand results? A Texas Hoosier is not particular about the spoon, a cow's horn will answer in case of necessity. Texas is a big State, her bee pasturage grand, and

with a continued honey flow from 30 to 50 days, there is nothing "unreasonable" at all about our reports. Did not Dr. J. E. Say (a noble specimen of Texas' bee-keepers) say at the last National Convention, that he made an average of 300 lbs. per colony? J. S. Tadlock, of Luling, had 247 lbs. per colony, and had nearly 500 lbs. from one. This is not all; the grand news will be wafted from Maine to California, that Texas has produced a ton of honey from a single colony, and its legitimate increase, in one year, and when she does this, do not say it was unfair. Let us have a little more charity. Are we not inmates of that great hive of nature? And if my spoon is a little larger than the Iowa spoon, by 62 lbs., just go to work and make it larger.

Dresden, Texas. B. F. CARROLL.

[Mr. Carroll is referred to page 115, where, we think, he will find a satisfactory explanation.—ED.]

Mice as Bee Enemies.

On page 96, Mr. H. J. Northrup tells how Mr. O. has wintered his bees successfully for 12 years. That is good; but here it would be a "sweet jubilee" for the mice. We have, besides the common mouse, a timber or field mouse. It is dark on the back, brown on sides, white throat and belly, with fur on the upper edge, and rather short tail. We also have the mole with its peaked nose; that pushes its way through on top of the ground under the snow, grass or leaves. Have they those three to contend with in winter among their bees in Lansingburgh, N. Y.?

Limerick, Ill.

E. PICKUP.

Feeding Poor Honey in Spring.

I began the season of 1882 with 4 colonies, in box hives; have taken 440 lbs. of comb honey from them and their increase (mostly from the increase) in 1 and 2 lb. sections. I have sold nearly all at about 16 cts. per lb., and increased them, by natural swarming, to 13. But, owing to the lack of experience, they were rather light in stores, the sections having been left on too late to give them stores enough for winter. I had to feed 80 lbs. of sugar. I had everything to buy for working the apiary, most of which will come in use this season. My expenses were \$95, and counting the goods on hand at a low price, and cash received from sale of honey, I have made \$16 on the investment, without setting any price on the bees; if they winter through, I shall be that much more ahead. Some of the colonies appear to be wintering all right, packed in sawdust with chaff on top of frames. Two colonies I packed with sawdust on top of frames, as an experiment; one of which suffered with dysentery, until the 15th, when the weather became warm enough for them to fly with safety. The colonies in the box hives I left on the summer stands, without packing. They have suffered with dysentery, and one is dead. It did not do well last summer, sent out two

swarms, but did not gather any honey in sections; the combs were very wet, and some were a little moldy. There was 12 lbs. of honey in the hive, and 2 combs contained some capped brood in the centre of cluster. About three weeks before I found they were dead, they seemed to be all right. The weather turned cold, and, on the 14th, I found them dead. I think their death was caused by too much dampness in the hive, as it was very wet throughout. Will it do to feed this honey to the bees in the spring? The combs showed some signs of dysentery, and some are a little moldy.

ALFRED GANDER.

Adrian, Mich., Feb. 19, 1883.

[Yes; when the bees have a chance to fly you can feed them almost any kind or quality of honey without danger.—ED.]

Will Freezing Eradicate Foul Brood?

I would like to inquire, through the BEE JOURNAL, of Mr. D. A. Jones and others, in regard to freezing hives, combs and honey that contained foul brood last summer. The bees cleaned it out of the comb after they stopped brood-rearing in the fall, and the bees were changed into new hives. Would it be safe to use them next summer, after being frozen as hard as they have been this winter? Mr. Jones claims that boiling will kill it. Is not freezing as good as boiling?

O. E. BURDEN.

Birdsall, N. Y., Feb. 24, 1883.

Wintering Bees in Dakota.

I removed the snow from my bees to-day, and found 4 colonies out of the 11 had died; 2 were in Simplicity hives, 1 American, and the other a Langstroth that had no upper story. The rest of the colonies, in Langstroth hives, were all right, and the day being warm and pleasant, the bees had a good flight, the first since Nov. 20. They seem to be in splendid condition. I do not want any more Simplicity or American hives to winter bees in. I am satisfied out-door wintering, with hay packing, in Langstroth hives, is the best way.

WM. W. EASTMAN.

Yankton, Dakota, Feb. 28, 1883.

Old Foggy Notions.

On page 42 of No. 3, of the BEE JOURNAL, I am made to say 33 colonies, when it should be only 23. In the fall of 1881, at the time when I should have been preparing my bees for the winter, I had to serve 3 weeks on the jury, but we had a mild, open winter, and, contrary to the general ideas and practice, I worked with them many times during the winter, and with no bad results, and this last fall I was summoned as a witness on two different occasions, and my bees were again neglected. I am anxiously watching for a nice warm day, that I can look after their wants, as they are keeping up a loud roaring in their sheltered location. As we, in this section, have but little else than ignorance to report concerning bee-culture, and believing that none but

true reports should be made, I will give your many readers a faint idea of it. When I launched out in the business I had a partner, and we were getting bees in the timber, and my partner, one day, asked a German boy if he had seen any bees? The boy replied that his brother-in-law had some pretty nigh a soda bottle full already; that he runs and catches them on the flowers, and when he gets that soda bottle full he will make a colony, and then they will make honey in it. An Englishman, about four miles east of me, had some buckwheat, and he discovered the bees working on it; he then hurried down to his neighbor Johnson, that he could learn if they would injure the grain. Johnson told him that he could not see why they would not injure it, that they were certainly robbing it of the substance that formed the grain. He very hurriedly got a brush and went in to drive them out, he said, but as all can imagine, they were not to be driven.

Illinois City, Ill. E. F. CASSELL.

Damage to Bees by the Flood.

The flood has subsided, and now I know the amount of damage done to my bees. I had 85 colonies drowned outright, besides some damage to the others from taking them out during a cold rain; the water was $4\frac{1}{2}$ feet deep in my bee house. Pretty severe, but I will show you before the end of the year what I can do in the way of building up.

L. H. SCUDDER.

New Boston, March 2, 1883.

Bees in Fine Condition.

I have 72 colonies on the summer stands, in the Langstroth hive, and 36 in the cellar, and all are doing well; all alive yet, and not one showing any signs of dysentery. Will say to S. G. Holley he has a young apiarist, but I have a little girl of 3 years who can open my observatory hive, and find, and point out the queen, among other bees, to visitors. I suppose they would make a good convention of bee-keepers of themselves.

DANIEL WHITMER.

South Bend, Ind., Feb. 27, 1883.

The Prospect in Kentucky.

The past winter, with us, has not been as cold as we sometimes have it, but it has been one of the most disagreeable ones we have experienced for several years. The changes have been frequent and very sudden, consequently our bees have suffered severely. It is the general practice with us to winter bees on the summer stands, and often without any packing or protection whatever. The fall was very favorable for gathering in winter supplies, consequently our bees were strong both in numbers and supplies. But few colonies have died, yet all have dwindled very rapidly, and many will be so weak in numbers as to necessitate wintering with others. The 14th and 15th were beautiful days, and warm as May, and our little pets made full use of them. In looking through several colonies I found brood in all stages, and queens busy. Since then they have not been per-

mitted to fly. The prospect, however, for a good honey crop is very favorable. As we had but little fruit last year, our fruit trees will be sure to furnish an abundance of bloom. Also, black locust, basswood and other honey producing trees. But most cheering of all is our prospect on white clover. The winter has not injured it in the least; our fields are densely sodded with it, which, even in these few warm days we have had, is showing cheerful signs of starting. Last year, at this time, I could scarcely discover it at all, yet it came out well. With these hopeful signs from vegetation, if we can get our hives strong by the first of May, we hope to roll up a list of statistics which will make Dr. Miller, and that man with his 500-pound colony, "come again."

L. JOHNSON.

Walton, Ky., Feb. 25, 1883.

Experiments in Wintering.

To-day has been nice and warm. Bees all out. I made an examination and found that out of 12, with no protection, 5 had died; that out of 5, with outside protection, 2 had died; that out of 80, in chaff hives, 1 had died. There are signs of dysentery, but I think to-day's flight will cure that trouble, and, as I do not expect "spring dwindling" in chaff hives, I have commenced whistling! How is chaff with you over in Indiana, Mr. Kite?

C. W. MCKOWN, 60-130.

Gilson, Ill., March 1, 1883.

A Profit of \$37 Per Colony.

I commenced the season with 25 colonies, Italians and hybrids, and have taken 5,000 lbs. of honey, mostly extracted, and doubled the stock. I have sold most of the honey at an average of 16 cts., making me a profit, the way I figure it, of \$37 per colony, spring count.

MILF SMITH.

Greenwood, Polk Co., Iowa.

Sawdust Packing Ahead.

Our bees flew well yesterday and to-day, for the first time since Nov. 15. From 137 colonies packed in chaff and sawdust, 2 are dead. Nearly all are in prime condition. Sawdust is ahead of chaff for packing. Colonies, with entrances $\frac{1}{2}$ inch wide by 11, wide open all winter, are in far better condition than those with entrances $\frac{3}{8}$ in. by 4.

H. D. BURRELL.

Bangor, Mich., March 1, 1883.

The Season in California.

Our bees have wintered splendidly. The white willow commenced yielding honey, this winter, November 26, fully 3, if not 4 weeks earlier than usual, and it has yielded most abundantly; so much so, the queens are crowded out (in the strong colonies) and the extractor must be used or we will have light swarms to go into the mustard harvest with. Alfalfa is coming into bloom, but will not be at its best for two weeks yet. We are well pleased with our hybrid Holy Lands; they are rustlers. I speak of them as hybrids, for we have the second generation of queens, mated both times

with Italian drones, and the progeny (so it seems to us) possess many of the desirable traits so much looked for in the "coming bee." We think we have had rain sufficient to give us a moderate harvest in the valley (rain fall up to date 6 inches), but this will give us no sage honey at all. Last year we had four inches of rain after this time, so we are hopeful yet.

A. W. OSBURN.

El Monte, Cal., Feb. 25, 1883.

Convention Notices.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.

Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nelle's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

The Eastern Michigan Bee-Keepers' Society, will hold its annual meeting in Detroit, April 3, in Abstract Hall, commencing at 10 a. m. An interesting meeting is expected, and bee-keepers are requested to send items or questions of interest to the secretary in time, that they may be announced previous to the meeting.

A. B. WEED, Sec.

75 Baggs St., Detroit, Mich.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address (Prof. A. J. Cook), on Wintering Bees. Essays: S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. WOOD, Sec.

North Lansing, Mich.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Several correspondents ask if it is essential to write only on one side of the sheet of paper when preparing an article for the JOURNAL. For us, it is just as well to write both sides, and saves postage in sending it.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., March 5, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 9c. here. BEESWAX—It is quite scarce. 1 lb. paying 30c. for good yellow wax, on arrival; dark and off colors, 17@25c.

A. L. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@15c. on arrival. BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@14c. Extracted, 8c. to 10c., according to color.

BEESWAX—32@33c. per lb. for good.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Offerings of comb are mostly of ordinary quality, and holders are disposed to close out at concessions. Market for beeswax is quite firm, with stocks quite limited.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9½c.; dark and candied, 5@7½c.

BEESWAX—We quote 27½@32½c.

STEARN'S & SMITH, 423 Front Street

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16c., strained, at 6½@7½c., extracted at 7½@8½c.—lots in small packages, more.

BEESWAX—Scarce, firm; quote choice at 28@30c., dark at 22@24c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 19@21c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 9@10c. in bbls. and 11@13c. in cans.

BEESWAX—Scarce, 28@30c.

A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Choice to fancy white clover honey continues scarce and dull, but buckwheat and extracted honey slow and irregular.

We quote: White clover, first quality, 1 lb. boxes, 24@25c.; fair to good, 22@23c.; buckwheat, 15@17c. Extracted, clover, 10@13c.; buckwheat, 9@10c.

BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly.

Western pure, 30@32c.; southern, pure, 31@33c.

D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Notice.—Bee-Keepers, we call your special attention to the advertisement of Champion Bee-hive Manufactory. 2t

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

We have a few copies of our pamphlet entitled "Bee Culture" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Important to Bee Keepers

Our New Book is now ready for Delivery.

THE ONLY WORK DEVOTED TO QUEEN-REARING EXTANT.

Every bee-keeper should have a copy at hand, as it not only gives

MY NEW METHOD OF REARING QUEENS,

but also the results of

Twenty-five Years' Experience as a Practical Apiarist.

The work also contains an essay, by one of the most practical, prominent and successful bee-masters in New York State, on

The Best Management of the Apiary

to obtain the largest amount of surplus honey, including preparing for and marketing the same. Also, an essay on

The New Races and Coming Bee,

by a former superintendent of the queen-rearing department of the apiary of D. A. Jones, Beeton, Ontario.

The work contains 150 pages and is intended as a "handy book" for bee-keepers, and much that is new and valuable never before published, will be found by a perusal of its pages.

Price (bound in cloth), by mail, \$1.00.

Enclose the money in presence of the postmaster at my risk. Those who so desire may remit receipt of book.

HENRY ALLEY,

Wenham, Mass.

CHEAP! CHEAP!

LANGSTROTH HIVES! SIMPLICITY HIVES!

All kinds of hives and surplus comb foundation, etc., etc. Having superior advantages for the manufacturing of hives and of procuring lumber low, I can furnish very low rates.

Send for descriptive circular.

A. D. BENHAM,

Olivet, Mich.

10A1f

WANTED An expert, possessing the necessary credentials, to act as manager, with or without a share, in establishing an apiary at Macleay River, in New South Wales. Address terms, etc., to the undersigned, from whom other information may be of tained.
A. V. HIGGINS, E. Kempsey, Macleay River, New South Wales, Australia. 101f

POTATOES AND STRAWBERRY PLANTS!

Send for Circular and Price List of the "Jordan's Prohibe" Potatoes, and "Big Bob," "Nigh's Superb," and "Wilson's Albany" Strawberry Plants, to J. D. KRUSCHKE, Sidney, Ohio. 10A1f

THE BRITISH BEE JOURNAL

AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. Rev. H. R. PEEL, Editor.

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 a year.

THIS PAPER may be found on the Co.'s Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in NEW YORK.

ESTABLISHED IN 1861

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

To Our Correspondents.

"Every day and hour," at lightning speed, over every railroad centering in this great city, come letters to the BEE JOURNAL from all parts of the world—east, west, north and south of this American continent, as well as from Europe, Asia, Africa and Australia. (A few days ago, one mail brought us foreign letters from England, France, Sweden, Mexico and Australia.) Letters of business or inquiries which call for answer by return mail. Letters of praise or blame, of approval or disapproval, of commendation or condemnation of something in the BEE JOURNAL! Letters to the Editor, either kind and complimentary or full of malicious abuse, which are intended to excite to enthusiasm or goad to desperation!!

Of course, we know the Editor must be cool and collected at all times, but to talk of his "easy chair" is a mockery.

During the winter months, many bee-keepers have little else to do but read, criticise and write to the BEE JOURNAL—and the number of communications on hand now, is simply overwhelming. In order to accommodate as many as possible this week, we have determined to omit the usual editorials, etc., and, "without further ceremony," present our readers with as many letters and communications as we can crowd into the paper. We will give all, as fast as possible. Some have concluded that their articles have been consigned to the waste basket, and ask for our reasons for doing so; others demand their return, etc. Exercise patience, eat a little more honey to keep good-natured—omit "stings," and all will go well in a few weeks.

SELECTIONS FROM OUR LETTER BOX

The Coldest Yet in New York.

The thermometer stood at 16° below zero here this morning, which is the lowest, so far, this winter. Bees had a partial flight 3 days ago, but, as the wind was strong, many were lost on the snow. They had been confined so long, that "fly they would," except a few colonies which were banked up with snow. One colony is no more, and 3 or 4 others are in bad condition, having the dysentery. Those in the cellar are quiet and nice, so far.

G. M. DOOLITTLE.

Borodino, March 5, 1883.

Bees All Right.

My 44 colonies all answered to roll-call to-day. It has been a very cold winter here. Bees crawled up among their combs on Dec. 13, and remained there until to-day, March 4, when they had a good fly. C. E. MILLER.

Justus, Pa., March 4, 1883.

Chaff for Wintering.

I have looked over my 135 colonies; they are all right; they are clean and nice except 3 or 4 that have commenced breeding; which have some dead bees, and look demoralized somewhat. I would say to Mr. Christianity that my chaff has "come it," so far. Some correspondents think brood a good sign. I think it a sure sign of "spring dwindling."

E. B. SOUTHWICK.

Mendon, Mich., March 6, 1883.

My Report for 1882.

I increased from 15 to 53 colonies, mostly by natural swarming, divided a few early in the season. Took off 1,000 lbs. of comb and 1,150 lbs. extracted honey. I am using the "Common Sense" hive. My bees are wintering well on their summer stands without protection. H. W. HITT.

Merritt, Ill., March 7, 1883.

Letter from Florida.

The weather here is warm and delightful; the orange trees are in full bloom, with the huckleberry, yellow jessamine, willow and other flowers, afford the bees excellent pasturage, and they are making good use of the opportunity to store honey. Brood-

rearing is going on fast, and the prospects are good for swarming by the first of March. We have been visited by "Northern Lights," in the shape of O. O. Podpleton and wife, of Williamstown, Iowa; they left here last week for Lampa and the Gulf Coast, previous to returning home, leaving behind them a number of friends and well wishes, besides much valuable information pertaining to practical bee-culture. H. MITCHELL.

New Smyrna, Fla., Feb. 18, 1883.

Right and Clear.

I desire to publicly thank Dr. Southwick for his manly utterances, on page 127, of the BEE JOURNAL for March 7. The contrast between the Doctor's clear vision and that of the near-sighted who cannot tell precisely about the property rights of others, is positively grand. J. M. SHUCK.

Des Moines, Iowa, March 8, 1883.

Bees Wintering Well in Massachusetts.

My bees are all on the summer stands, and wintering well. They had a fine flight on Feb. 17, the first since November. The glass ran up to 59° in the shade, and 79° in the sunshine. I am testing a new feeder; it is placed under the cushion. The bees can take the food from it without leaving the cluster, and the feeder can be refilled without disturbing it or the bees. I find it an actual necessity, as many of my colonies are short of stores.

HENRY ALLEY.

Wenham, Mass., Feb. 24, 1883.

Bees All Right in Iowa.

The winter is beginning to disappear; the snow is gradually going off, still now and then we have a cold morning. It was 4° below zero on March 7; but it is warmer to-day. Several days, lately, the bees that were on the summer stands, flew out; many that were unprotected are dead. Those in good cellars are all right yet.

J. W. SANDERS.

Le Grand, Iowa, March 8, 1883.

Large Yields of Honey and Increase.

When I see reports of large yields of honey and great increase of bees, I always know what I think of it. In his book of "The Hive and Honey Bee," Mr. Langstroth says that a large increase of bees and a large yield of honey cannot be had at the same time—and I am satisfied that he is right. WM. ROBERTS.

Vaughansville, O.

Bees in Splendid Condition.

Our first step, after purchasing 40 colonies of bees, in box hives, was to send for the ever-welcome and indispensable BEE JOURNAL. Our apiary is on an elevation, known as East Hill, descending to the west, $\frac{1}{4}$ of a mile from the beautiful city of Elmira. From our apiary every part of the city can be seen. Near by is the Chemung river (local name); on either hand, as far as the eye can penetrate, lies the valley of Chemung, teeming with a busy population, but without a bee-keeper for miles around. We have (for the want of a better place) wintered our bees in a plastered room. I succeeded in keeping them very quiet until the latter part of February, when I was compelled to move them to their summer stands. They are in splendid condition, and I hope to be able to give a good report in due time. No expense or labor will be spared to accomplish our purpose, which is to have as fine an apiary as can be found in New York. We shall use the two-story Langstroth hive. Which is the best time to transfer to the new hives? I have transferred early and late, but did not register the results.

COLEGROVE & BEACH.

Elmira, N. Y., Feb. 25, 1883.

[The best time is during fruit bloom; for there is less honey in the hives, and fewer bees. They will more readily fix up the combs when they have some honey to gather.—ED.]

Bees Saved a House.

My bees were on the roof of my house, at Shawneetown, Ill., during the great flood. They endured the waves and high winds, and are all right. Had it not been for the 140 colonies on the house, it would have floated off, as many other houses of similar size, in the neighborhood, are gone.

R. CADLE.

Mt. Vernon, Ill., March 1, 1883.

Cellar Wintering Snits Me Best.

We are having an unusual cold winter here. It commenced snowing sometime in December; the ground has been covered ever since, and now, at present writing, is, I think, about 18 inches deep, if it was not drifted. I think it will be just as bad on bees that are out of doors as it was two years ago, and I expect to hear of as many dying as then. Some of my neighbors, that have a few colonies, tell me they are nearly all dead. I only have 11 on the summer stands; 9 in chaff hives, and 2 in Simplicity hives, without any protection. They are both alive, so far, but one of them has been in the upper story on five combs, and are about one-half dead. I have brought them into the house, that is, the top story with the bees; the lower story has 10 frames filled with sealed honey and ice; this will learn me not to leave any more bees in the top story for wintering. One of the colonies in chaff hives, is dead, and another one or two have the dys-

entery. I have 42 in the cellar that appear to be getting along finely, and I have about come to the conclusion that cellar wintering suits me best. My cellar is very dry, and I have a stove pipe attached to the outside door, and have ventilation inside also. One of my neighbors found a bee tree, and I happened along just they had taken the honey; about one-half the bees were clustered in the side of the tree, where they had taken the honey from. I looked at them a while, and said to the parties, it looked like a shame to let them freeze, as the thermometer was, at that time, below zero. I walked on home, studying about the matter, and when I got there I told my wife about them, and she asked me if I could not save them? I told her I would try, and so I picked up a market basket and some flannel cloths, and a garden trowel to scoop them up with, and went back and brought them home, warmed a couple of frames of honey and put them in a hive; kept them by the stove all night, and next morning put them in the cellar; they are doing finely, and I calculate to make a good colony of bees out of them.

MILO SMITH.

Greenwood, Iowa, March 1, 1883.

Bees in the Cellar All Right.

I commenced the season, June 1, 1882 (which was the poorest for some years), with 20 colonies, in poor condition, owing to the cold spring; increased to 50; extracted, July 1, 250 lbs.; fed back about one-third, to late swarms; the balance is my surplus yield. I put 50 colonies in the cellar under the house; it is a dry one, 65 feet above high water mark. I manage somewhat on the plan of Mr. Ira Barber; I threw in and saturated my cellar with 6 or 8 pails of water, before putting in the bees; it has no ventilation, except a door to the kitchen, to be opened when needed. To-day, I cleaned off the front of the hives, and swept the cellar bottom clean, not getting 1 pint of bees. I used a lamp, and, during the operation, not a bee flew out. A light roar only was heard, but all answered to "roll call." I never knew bees so quiet after three months' confinement. J. B. IDE.

Climax, Mich., Feb. 20, 1883.

Bees Down in Maine.

We are having a hard winter for bees down in Maine. The weather has been cold ever since Dec. 1, and it looks now as though we might have another grand disaster, like the season of 1880-81. Part of our bees are in single hives, and part in chaff hives; the chaff hives and a part of the single hives were covered, so as to stop the entrance up, by the first snow that came in November, and have been covered ever since, and the bees have had no flight since the first of November. The other hives are in a sunny place, and, in the middle of the day, bees have flown a good deal through the winter. They have dwindled badly, and show signs of dysentery. In three of them, the bees have left the combs and are occupying

the bottom boards. Those in the hives under the snow, that have not flown the entire winter, are looking all right, and have not consumed half as much honey as those that have been flying. Such a winter as this makes me yearn for a cellar to winter my bees in. Will some one, having wintered bees in a cellar with success, give us a rousing article on how to ventilate a damp cellar. My cellar is not what might be called a wet one; there is a spring in one corner, so there is water in the cellar at all times, and still the bottom of the cellar is not wet. Is there any way to ventilate such a cellar, so that it would be a proper place to put bees, and, if so, how? Will some one give plain, simple instructions how to do it.

J. B. MASON.

Mechanic Falls, Maine, Feb. 25, 1883.

Lost One Colony.

I have lost one colony, so far, this winter, the cause of which we cannot account for. They had about 20 lbs. of honey left. Our bees are all in improved Quinby, chaff-hives, same as they were in 1880-81. Then we did not lose a colony. The others are all right. I do not expect to lose any more. I should be glad to see more letters from lady correspondents. I have just read Mrs. C. J. Allison's experience, on page 110. Let us hear from more lady bee-keepers.

S. S. BRISTOL.

Galesburg, Mich., Feb. 26, 1883.

No Profit Without the Bee Journal.

I have read the BEE JOURNAL for over 18 months, and cannot do without it. I have kept bees for 40 years, but I obtained no profit until I commenced to read the JOURNAL, and there saw that box hives were not the kind of hives to use. I commenced, last spring, with 22 colonies in boxes, and all kinds of hives, except the Langstroth. I got 24 Langstroth hives and filled them, mostly by natural swarming. I have now 44 in the cellar; they seem to be all right, yet have not had a flight since Nov. 15. I got 100 lbs. of surplus comb honey this year. I have a farm of 560 acres, and keep about 150 head of cattle, but I am 59 years old, and expect to make bee-keeping a part of my business. I shall sow nearly $\frac{1}{2}$ bushel of sweet clover seed this spring.

E. S. HOVEY.

Swanton, Iowa, Feb. 28, 1883.

Remedy for Bee Stings.

Bees did not have a good fly from the time winter set in (which was about Nov. 15) till Feb. 16. Mine are all in good condition except one, in a single-walled hive, which is very uneasy, and has the dysentery slightly; the rest are in Simplicity chaff hives, with inch holes in gables of covers. The single-walled hive had only a hole at one end of the cover, and consequently the chaff packing above the cluster was very damp, so much so that I changed the packing and raised the cover by putting nails under each corner. This shows the necessity of

sufficient ventilation above the packing to let off any excess of moisture. $1\frac{1}{2}$ or 2 inch holes would be better than 1 inch; the latter not being sufficient, in my chaff hives, to keep the chaff as dry as I would wish. Here is another remedy for bee stings, taken from "Peterson's" for March: Honey-suckle—*Lonicera Japonica* and *L. Caprifolium*. Ornaments of our gardens, lawns and piazzas. A syrup prepared from the sweet-scented flowers has been used with benefit in some cases of asthma. The expressed juice of the leaves is used to relieve the pain and inflammation of bee stings. Who has ever tried it?

JOHN S. SNEARLY.
Williamsville, N. Y., Feb. 25, 1883.

Drones Now in the Hive.

My bees were shut up from about Nov. 1 until Feb. 16; they flew on that day. I have been sick and confined to the house since Jan. 4; on Feb. 16, it was very warm and pleasant; in the afternoon, about 3 o'clock, I went out to look after my bees. Upon looking at one colony, having a black queen, mated with an Italian drone, that did well last summer, I noticed a drone leave the hive. To satisfy myself that I was not mistaken, I sat down to watch for his return. In about 5 minutes 4 drones entered the hive. I have had some experience with bees, and have read a good deal, but never noticed any account of drones this time of year. I have 22 colonies; they looked all right on Feb. 16, there were no signs of dysentery; they looked slim, and were active.

H. M. GROVE.
Titusville, Pa., Feb. 28, 1883.

[Drones are sometimes tolerated in the hives all winter, if the colony is queenless; which yours probably is.—ED.]

Preventing Increase.

In reply to J. B. Hall, I will state that I have practiced the method of disposing of natural swarms, as given by Prof. A. J. Cook, on page 474, of the BEE JOURNAL for July, for several years, and found it a perfect success, before writing it for *Gleanings*, 4 years ago, when Mr. Root said it might do, but was sure they would swarm and swarm over again. How did he know when he had never tried it? Does Prof. Cook claim the idea as originating with himself?

Carson City, Mich. HIRAM ROOP.

An Enthusiastic Beginner.

Last spring I commenced with 2 colonies, and made them into 10, but got no honey, the season being poor. I have taken great interest in this (to me) new business. Have read enough, the last 12 months, to set up a dozen bee-keepers, and remember about half enough for one. I lately read the last year's volume of the Weekly, the loan of which I got from a friend, and was particularly pleased with the letters of Messrs. Heddon, Doolittle and Hutchinson. Mr. D.'s plan of collecting the valuable, as mentioned

in the issue for Feb. 14, is good. I have my bees in a bed room, and think they are all right, so far. They have been very quiet, still quite a number comes out to die. I am longing to see the industrious little creatures at work again. I hope that the coming season will be good, and that we will get some honey. A great depth of snow has been covering this part of the country, but a thaw on the 16th and 17th turned, perhaps, a third of it into water, which sunk into the ground, there being little or no frost below.

F. MALCOLM.
Innerkip, Ont., Feb. 20, 1883.

The Bees in Cellar All Right.

I have just finished carrying out the bees to-day. All colonies are alive, and in good order. I put them in the cellar on Dec. 7. I have 34 colonies. I started, last spring, with 14, all in Langstroth hives. I feel quite provoked, after reading in the BEE JOURNAL about the dimensions of the Langstroth hive to find, on measuring my hives, that they are too small; the frames are only 16x8 inches, and the brood chamber contains only 1,800 cubic inches, in the clear.

JOHN J. STENGER.
Fort Madison, Iowa, Feb. 23, 1883.

Bees Easy and Quiet in the Cellar.

I commenced, last spring, with 30 colonies; some were very weak. I had to feed most of them, up to June 1, to save them from starvation. I got 3,200 lbs. of honey (2,000 lbs. of comb, and 1,200 lbs. of extracted); increased to 41 colonies, which are in the cellar and seem to be wintering nicely; they are quiet. They became somewhat restless about two weeks ago, when it was raining, and the snow melting off. I put a ball of snow in front of each hive, in the portico, and as it melted they got water from it and became quiet, and have been so ever since. The thermometer stands at 65° to-day.

MRS. A. B. WINDER.
Grand View, Iowa, March 1, 1883.

Too Much Pollen.

Ten of my colonies are all right, so far; 5 have died (1 starved, the other 4 had the dysentery); they were the strongest colonies I had. Those fed with granulated sugar are all right. One of the colonies that died had the hive full of bees on one side; it had a comb with pollen, and all the bees on that side had the dysentery; and an awful mess there was. The bees on the other side of the hive, without pollen, were as dry as they are at mid-summer. Next fall I shall feed them all with granulated sugar syrup, and take out all the pollen.

Racine, Wis. HUGH WILLIAMS.

A Cold, Cold Winter.

We have had some very cold weather, Dec. 7, it was 26° below zero; Jan. 21, 40° below; 22, 36°; 23, 34°; and Feb. 5, 29°. We have had two days in this month that it has thawed, and the mercury reached 43° above zero. We have 3 feet of snow

on the level; we had to shovel snow from the roofs of our buildings, to keep them from being crushed, by the weight. I have lost 1 colony of bees with dysentery, and I am fearful for the rest, if we do not have a day soon that they can have a good flight. They have been housed for 114 days. The BEE JOURNAL is always welcome, and I read it through before I leave it. I think we will have a good season for honey, in this part, for the ground is well protected, and no frost in it. We hope for the best. I shall be glad when I can hear the hum of my pets, and see them bringing in pollen for their perpetuation.

EDWIN BUMP.
Marshfield, Wis., Feb. 21, 1883.

Bees Flying To-Day.

The mercury is 50° above zero, and the bees are now flying a little, for the first time since Nov. 11. My bees have wintered well, so far; they have been under a snow drift, all winter, with the snow kept away in front, so that they could get fresh air. I think we have a pretty even temperature up here for wintering bees on the summer stands. The coldest it has been is 10° below zero twice, and it run up to 27° above zero before noon both days, and it has not been higher than 45° above. Most of the time it was from 35° to 40° above zero.

G. L. PRAY.
Petoskey, Mich., March 1, 1883.

Bees Wintering Well.

I put the bees in the cellar Nov. 29; temperature about 35°; took them out for a flight Feb. 14, all wintering well, except one, which had the dysentery very badly. I removed all their combs and gave them clean ones, and fed sugar, saturated with honey. They are doing well now. Bees consumed very little honey; I used no chaff cushions or quilts; I raised hives about $\frac{1}{2}$ an inch off the bottom board, putting sticks under the corners, and kept the cellar perfectly dark.

R. GRINSELL.
Baden, Mo., Feb. 26, 1883.

Cellars Best for Wintering Bees.

On Dec. 6, 7, 1882, I put 130 colonies in the cellar. I had to pile them 3 high, in order to get them all in. I put 100 on summer stands on Feb. 28, 1883; the other 30 on March 1; all are in fine condition, except one, which had the dysentery some, and had lost about half the bees. If sugar syrup and chaff can beat that, let us hear from them. I still vote in favor of the cellar to winter in, if intelligently done.

J. E. HUNTER.
Wyoming, Iowa, March 3, 1883.

Prospects are Good.

The thermometer registered 65° at sunrise to-day. The bees have been flying lively, after a confinement of 100 days. They began to show signs of dysentery, but all answered to roll call, but one, which starved with 25 lbs. of honey in the hive, because I neglected to give them more bees in the fall. My bees consumed but little

honey, and the combs are bright and dry. They were wintered on the summer stands, as I think all bees should. More bees are lost by moving back and forth than in any other way. By shading the entrances, the bees will not fly except when it is warm enough for them to return. Prospects are good for white clover. I shall sow 25 acres of alsike and sweet clover, in wheat, in a few days.

JOHN A. WILLIAMSON.

Lodge, Ill., Feb. 16, 1883.

Packing Bees in Sawdust.

Last autumn I packed 9 colonies, on Mr. James Heddon's plan, and one two-frame nucleus on Mr. D. A. Jones' plan. On Feb. 16, they had a good cleansing flight; they are all strong, so far, with but few dead bees. Even the two-frame nucleus is strong and lively. Last autumn I put two frames, full of honey, one on each side of them, and two division boards on each side. They are in a small space in the hive. I think that packing in sawdust is the best plan to winter bees, for this was a very hard winter. I think that my bees will winter through all right. I made a bridge of Langstroth's portico, for winter passage for the bees. Will it do to leave them packed until May 1?

WM. ROBERTS.

Vaughansville, O., Feb. 17, 1883.

[Yes, sir; keep them packed until just before they need surplus boxes. If thin cloth is over them, exchange this for a solid board cover, or some cloth they cannot gnaw.—J. HEDDON.]

Large Yields—A Correction.

In giving the additional number of pounds for the 192½ sections at the rate of 1½ lbs. for every 20 sections (see page 107), 143¼ lbs. should be 142½ lbs. (Perhaps 14½ would be nearer right, making the aggregate 399½ lbs. A mistake of the printer.) Another slight mistake occurred in the first column: "On" instead of *in* each cover. The covers are 7 inches high, and we use the inside of the 4 sides of the rims for recording slates. We were pleased to see Mr. Caldwell's remarks on the same subject; he presents it in still a different light, and we desire to add a thought or two Mr. F. overlooked. From the yearly reports of our most successful bee-keepers, Mr. F. will see that these large yields are very rare cases. Besides, the closest attention of the apianian, the co-operation of the most favorable circumstances is necessary to produce such results. Among the many bee-keepers of the country, there is only now and then one, who obtains such a large yield, enabling him to give one of those so-called "exaggerated reports," and this may be the only one in his life-time. Since 1875 we have kept from 100 to 200 colonies, yearly, and this is the only time that we ever had such a yield or anything near like it; we had several colonies that season, which overrun 300 lbs. considerably; but even that is such an exception that we hardly expect to see it ever repeated. We

would gladly give \$500, or twice that amount, to any one who could teach us how to always produce such yields, but we know that it is an impossibility, and will be as long as we cannot control nature.

Naples, N. Y. GREINER BROS.

When they Bloom.

Is white clover profitable as a honey plant, the same season, when sown in the spring? Will figwort or motherwort bloom the first season, when planted in spring? How long does it take to bring Rocky Mountain bee plant to a producing state?

Northboro, Iowa. O. E. MOORE.

[If sown early in the spring white clover and motherwort yield honey in the following June, and cleome (Rocky Mountain bee plant) and figwort in the July following.—Ed.]

Feeding in Spring.

Let me say to those who want a big yield of honey next season, to try feeding, as soon as bees can fly; if they have too much honey, take some from them and feed sugar syrup. I have tried it, and know the bees will pay back the cost with compound interest. Bees are wintering tolerably well. I have lost 1 out of 44. I expected to lose 3, and perhaps more. They had a good flight, and they needed it, on Jan. 27 and 28, and Feb. 7, 8, and 19; they have plenty of honey. I think they have consumed 15 to 20 lbs. already. I have 1 colony wintering with the hive raised 2 inches around, with coffee sacks on the frames, and they are coming through all right. I have 40 colonies in a dug-out, on a side hill, facing south, and banked up on the north and ends, with dirt, even with the top, and covered over with hay and boards. This winter I am trying cellar and out-door wintering. I think the latter will come out best, since the bees have had a good flight. WM. MALONE.

Oakley, Iowa, Feb. 23, 1883.

Light in Bee Repositories.

In conversation with an acquaintance of mine, a carpenter, who had made bee hives and boxes for his neighbors, he said he was ready to disagree with any bee-keeper that it is necessary to exclude light from cellars or bee houses wherein bees are kept in winter. He claims that it is natural for bees to be surrounded with light, as they are when in trees and hives when standing out of doors. He does not believe it necessary to make cellars and bee houses dark, so far as the light is concerned. If the darkness that is within the bee hive, is all that is necessary for the good of the bees, why not put windows in our bee houses, clamps and cellars, and make them as light as our houses? It might seem that I have read enough to have that question settled, but I do not remember seeing or hearing it explained why the light is objectionable to the inside of the bee house. Pretty much all the reason I can call to mind, is the fact that those

places are built without windows, and made as dark as possible. Of course, light attracts bees out, but is it not the temperature of the room which keeps them in the hives? On consulting Cook and Quinby, I see they both say a cellar or house must be made perfectly dark, but do not explain the particular reasons why. If "a little knowledge is a dangerous thing," then it is best for us, inexperienced ones, not to form too positive opinions. Such may be the case with my friend.

Ludlow, Vt. A. P. FLETCHER.

[Mr. Heddon promises us an article on the above subject, which will answer the questions asked.—Ed.]

Wood Separators.

Why not make them come the whole width of the section box? Then, if it cannot be done in making the separator, we can take our pocket knives and, with straight edge, trim out a notch in a few minutes, and the whole question of bee glue is solved, especially if you use tight-fitting cases and clamps.

C. H. DEANE.

Mortonsville, Ky.

Hives Full of Honey.

I started in, last fall, with 44 colonies; lost three; the rest are mostly very strong; wintered on the summer stands, by turning a box over the hive; nearly every frame is full of honey. Should I extract to give them a chance to breed up? I want to increase early. They commenced to carry in honey and pollen yesterday, March 4. I find my hive is too short: 15¼x11½x10 inches, side measure. Should I change? W. H. PEARSON.

Jarbalo, Kans., March 5, 1883.

[If the frames are full of honey, use the extractor to give the queen room. As you have started in so liberally, it will not pay to change frames.—Ed.]

Transferring Bees.

By his, Mr. Heddon's new process, filling the hive with frames of foundation, he tells us that he takes the drum box, approaches the box or queen to be transferred, and proceeds in the ordinary way to smoke, turn the hive "topsy turvy" and draw the bees up. Would it not answer every purpose to place the old gum or box on top of the frame hive and proceed to smoke and draw the bees down on the foundation frames? If the downward process will answer as well as the upward expulsion, a board, to cover the frame hive, could be provided, with a hole 7 or 8 inches in diameter, or larger, cut in it; place the box hive on it, and everything would be very convenient for business.

Highlands, N. C. E. E. EWING.

[The downward expulsion process, is not as good, efficient and speedy as the drum box and upward driving plan, I laid down in "Modern Transferring." Bees hive upwards much more readily than downwards.—JAMES HEDDON.]

Temperature to Make a Cold Winter.

G. M. DOOLITTLE.

On page 111, Mr. Wismer wishes me to say "what the thermometer will record for a mild winter, and what for a cold one." Two years ago the lowest point touched was 22° below zero, and during nearly five months the highest point was only 41° above, which was not warm enough for bees to fly. The average temperature was not far from 18° above zero; such is what I term a cold winter. Last winter (one year ago) the lowest point was 26° below zero, while, every few weeks, the mercury stood at from 48° to 60° above, which gave the bees a chance to fly. The average temperature of last winter was not far from 28° above zero. Although 26° below zero was the coldest of anything we had experienced during the past 13 years, still the winter, on a whole, was what I term a mild one. Occasionally, one or two extremely cold days do not materially injure bees, when it soon warms up, so that they can have a flight and take fresh honey inside the cluster, but five months of steady cold, as low as 18° above zero, is almost sure to work death and ruin for them.

Whilst the 26° below zero, a year ago, did not materially injure the bees, it was of great disadvantage to the apiarist, as it killed the fruit buds, to a large extent, and the continued freezing and thawing destroyed the clover. I have often noticed, here in New York, that our best yields of honey follow a cold winter, during which more or less of our bees perish, which, in fact, compensates for the loss of bees. During the present winter the mercury was down to 15° below zero on the morning of Jan. 10, and has been from 6° to 12° below several times since then. The thermometer showed 11° below on Feb. 23, at 8 p. m.

My bees have had no flight since Nov. 11, and many of them are beginning to badly feel the need of a cleansing flight; others are apparently in as good condition as they were when packed for winter.

The point I desire light on, above all others at the present time, is: How can I secure to *all* the condition enjoyed by the *few*? All were equal, as far as I could tell last fall, and all were packed alike. Those having bottom ventilation, with none at the top, are in the best condition, so far. I believe there is a difference in bees about wintering; for the bees from a queen, received from Texas last June, were the first to spot their combs; and at this time scarcely a handful of them remains, and they are in a deplorable condition.

I am studying, and experimenting with a view of getting some light on

this inequality of different colonies regarding wintering, hoping that I may gain some knowledge of the matter before my bees have to pass through another cold winter.

Borodino, N. Y., March 1, 1883.

For the American Bee Journal.

Pure and Dollar Queens.

JACOB SPENCE.

Intensely interesting have been the discussions carried on in the BEE JOURNAL on the many questions as to the various methods of apiary management. Particularly notable are the conflicting ideas entertained by even the wise and experienced breeders, on the virtues and comparative merits of the several bee races and crosses, with a view to producing the "coming bee."

The object of present reference to these various presentations of opinion is particularly to call attention to a point or two which others, no doubt, as well as myself, may have noticed, which these authorities appear to have overlooked or do not seem to have taken sufficiently into consideration.

First, Definitely to set forth what is to be squarely understood by the term "pure?" In fact, to some who have also paid attention to the subject, this idea of a "pure strain" seems not a very "pure and simple" idea—how far back pure? and then—where is the purity start to be discovered? The further back genealogy is traced, assuredly, the more *mixed* it looks. Every queen, as well as every (human or bee) subject, is reported as having two grandmothers, and, similar count, grandsires, and then every remove back, once more doubles the number, say, 4 *great*-grandmothers and 8 *great*-great, etc.—so that by the time we reach six generations (which some report as accomplished in one season) it is plain that we repeat *great* only four times we have, by correct geometrical progression, 64 female, and, no doubt, as many more male progenitors, of our last queen only a few months since! (and another generation back 128, etc.) now, *pure*—from which?

I confess, also, to some serious apprehension in the matter of breeding certain peculiar good and valuable characteristics, and, at the same time, that of the undesirable traits of the race, while retaining those desirable. This really looks like a rather up-hill undertaking.

Most physiologists would be likely to, at least, hesitate about guarantee against the cropping out, too, of some of the bad pranks of some of the great grand-parents, in the coming generations.

Most emphatically, however, am I in favor of shrewd, best-devised effort to breed in all practicable perfection. Taking advantage of "survival of the fittest," as well as all advanced appliances for controlling the provisions for propagation. "Natural" (and artificial) "selection," utilizing and guiding what is called instinct, much, doubtless, may be turned by skill to valuable account, and very deserving

of high commendation indeed are the assiduous efforts of our much esteemed, progressive queen-breeders. Yet may one respectfully presume that some of these may not be entirely beyond taking in good part a respectful suggestion in the line that they do not try to have themselves and all others accept as true, in this particular line, that "all things are possible to him that believeth" in himself.

I rather fear that the (so-called) "fixed type" will need fixing all the time. To me, pure stock, in this case, would mean very much akin to "in-and-in" breeding, and, for one, I do not want such purity. A queen, from percentage of good results, I would, indeed, like; hoping, too, that she may have exercised good taste in the selection of her royal mate. It may fairly be hoped that many of the good qualities, so very desirable, are likely to be largely secured by exercise of good taste and mature judgment of experienced apiarists, and, if by extra application, ability and skill, a strain can be produced so vastly improved as to be worth a fancy price, no one need be disposed to complain. However, accepting as true what is asserted by breeders of high reputation, "that dollar queens are reared, under proper conditions, from the most approved parentage," then I feel like taking such, when I need, thankful to the decent vender who CAN do, and honorably does all he promises; so am I disposed to vote dollar queens a boon to bee-keepers.

Toronto, Canada.

For the American Bee Journal.

Obtaining Queen-Cells for Nuclei.

P. L. VIALLO.

When the time comes, in spring, to start my queen-cells for queen-rearing, I pick out, in my queen-rearing apiary, the necessary number (according to the number of nuclei) of the strongest colonies, and mark them from No. 1, up. On the first day that I wish to start cells, I take out all the unsealed brood from No. 1 and give it to No. 5, or distribute it among those in which it will do the most good. The queen of this No. 1 is either caged, for further use, or used where required. In 5 days, when all the queen-cells are capped over, I take the frame of queen-cells out, and put it in a strong colony, to take care of the cells until they are due for the nuclei, which I rendered queenless and broodless, and mark it No. 1 A. I mark this differently, as it will take care of the cells of 5 others. I give No. 1 the queen and all the brood of No. 5, which is the one I have to start cells on that (the 5th) day. On the second day I take all the brood of No. 2 and give it to No. 6, or distribute it, as I did with that of No. 1, and, in 5 days, I give the queen-cells to No. 1 A, to take care of, and give this No. 2 the brood and queen of No. 6, and so on, with No. 3, 4, 5, etc.

Therefore, we see, that when we reach No. 5, on the fifth day after starting cells in No. 1, we give its

brood and queen to No. 1, from which we have just taken out the queen-cells. No. 2 received the brood and queen of No. 6; No. 3 that of No. 7, and so on, as we proceed giving the brood of the one we start cells in to the one from which we take the cells. When I reach No. 11 I render another colony queenless and broodless, to take care of cells, until they are due, that is for 10 days, as No. 1 did, which I mark No. 2 A. I give No. 1 A the queen and the brood of No. 2 A. By this method my colonies building cells are queenless only 5 days, and as they receive the brood of another, they are kept in good condition. Of all the colonies I used, this season (1882), for queen-cells, I have extracted an average of 75 lbs. of honey, and besides, got all the brood needed for keeping up my 4 and 5 frame nuclei, and they are, at this date, as strong as any colony in the yard.

This is a system of rotation, which may appear complicated, but when practised, takes less time and is more satisfactory than the system previously adopted.

So as to make it easy, I keep a record in a book, as follows:

No. of Colony.	Date brood is given for cells.	Date cells must be removed to colonies taking care of cells.	No. of Colony taking care of cells.	Date cells are due for nuclei.
1..	April 1	April 5	No. 1A	April 10
2..	12	6	"	11
3..	3	7	"	12
4..	4	8	"	13
5..	5	9	"	14
..	6	10	"	15
..	7	11	"	16
8..	8	12	"	17
9..	9	13	"	18
10..	10	14	"	19
11..	11	15	No. 2A	20
12..	12	16	"	21

Instead of marking the month as in above, I use only cyphers; for instance, I put it in my book 4-1 for April 1st, etc.

For my cells I use strips of brood, about 3 cells wide, and hang them cell down, under top bar of frame, and, under another bar, nearly in center of frame. I use but two strips of brood and only 1 frame to each colony. I use wires bent in this shape:

to hold my strips to the bars, so that a branch of it rests on top of bar and the other penetrates just under septum of strips of comb. I always use brood one or two days old for my cells, never eggs, for reasons that all practical beekeepers know.

The above is given for 1 colony a day, but the same method is followed for more. I use 2 a day to supply 250 nuclei with cells.

The above is about the substance of an essay read at the National Convention, Cincinnati, which mysteriously disappeared after it was read.

Bayou Goula, La.

How Shall We Report?

JAMES HEDDON.

This subject is interesting and important, and moves directly upon the interests of honey-producers. I wish to touch it, in a little different manner, from that upon which it has yet been treated. I wish to consider it a little more in the abstract. Nearly all have assiduously labored to point out to us the rights and wrongs of counting extracted for comb honey, or saying "honey" without telling which kind, or weighing up wood and glass, or piling 5 colonies into 1, or 1 into 5, all of which admonitions are in place and to the point. That is right, when we speak, let us speak the exact truth, not only in the letter, but in the spirit. Since we have come to the consideration of the truth in the spirit, does it not call to our mind an old and wise adage, that, "even the truth should not be told at all times." I think Prof. Cook once fully appreciated the force of this adage.

A few years ago, the Professor, in company with the Michigan State Treasurer, and plenty of good help and advice, I doubt not, secured an extraordinary large yield from 1 colony of bees. This being a "truth," immediate report was the next step. This report was an effect of the cause, extraordinary yield. This effect, like all other effects, in its turn became a cause, and like all other causes, produced its effects, which were as follows: Various patent hive vendors throughout the country incorporated this report *verbatim* into their benighted or humbug circulars, the effects of which were to deceive and rob avaricious and ignorant farmers who owned "skeps" of bees.

Its effects, as published elsewhere, like that of other large reports, was to entice many who could not succeed at anything else, into the profitable business of honey-producing.

We know how prone is human nature, especially those who are out of a job, and just those that we do not want, and who, for their own sake, ought not to attempt our business, to kindly "take" to "big things," readily donning the possibilities of genius, as the probabilities of their own sweet selves.

Suppose one of our ablest producers was seeking a location in which to practice his favorite calling, how much notice would he take from a big report from one hive, once occurring in that locality? Would he not ask, what has been the average yield from a whole apiary during a series of years? "Chaff does not catch old birds."

What can be the object in sending in these big reports, no matter whether false or true? If their authors have carefully obeyed the eleventh com-

mandment, viz.: "Thou shalt not be found out?" the effect is the same all around. I can conceive an answer to my question. The enthusiastic beginner, when struck with the semi-occasional honey shower, becomes unexpectedly and unaccountably possessed of a large surplus yield from his most favorably situated colony (why most favorably situated, he does not know), and his young enthusiasm fills him too full for containance, and out comes the report. As we have some bee-keepers, whose eminence sprang from reports of large surplus, is another cause for sending in the report, and these desires thoroughly test the integrity of the reporter, which, if found wanting in the least, has a tendency to stretch the already large yield to enormous proportions, weighing up wood, glass, tin points, etc., and, possibly, direct crookedness gets into the figuring.

It is a great error to immortalize a bee-keeper for a few large reports, especially from a few colonies. Continued authoritative reports of this kind are quite another thing, especially if made out by second parties. Such catering is not only unwise in the caterers, but tempting to honorable aspirations.

I do not honor the natural philosopher who attempts to astonish me with his new theories of gravitation, based upon his assertions that he threw up a brick and it is still going up, but I honor the Kepler who proves his theories to my reason, by his discovered philosophy; or the Spencer, who proves his social philosophy by the genius of his mighty brain, who never asks you to take his word for any thing, but proves his theories by recalling your attention in a philosophical manner to what you already know.

Let us give in the reports of our successes and failures, in the aggregate or extreme, only when we have the self-consciousness that the effects of our reports will do justice to all.

Dowagiac, Mich., March 3, 1883.

For the American Bee Journal.

Keystone Bee-Keepers' Association.

The bee-keepers of this portion of Pennsylvania are still at work. On the 23d day of November last, pursuant to a call, a few bee-keepers residing in the counties surrounding Lackawanna, met at the city of Scranton, and organized the "Keystone Bee-Keepers' Association," adopted a constitution and by-laws, and elected the following officers for the ensuing year, viz.: President, J. W. Fisher, Drinkers; Vice-President, W. H. Hull, Olyphant; Secretary, Geo. C. Green, Factoryville; Treasurer, Justice Akerley, Justice; and Assistant Secretary, Geo. H. Colvin, Dalton.

After transacting the necessary business, and selecting questions for consideration at the next meeting, the Association adjourned to meet at the same place Jan. 11, 1883.

At this meeting several questions of importance to bee-keepers were discussed, and other questions selected

for consideration. Several new members were admitted; the present number being 26. The admission fee is 50c; ladies free. The next annual meeting will be held in Scranton, on Tuesday, May 8, 1883. The questions selected for consideration, were: "The Production and Care of Surplus Honey;" "The Best Method of Wintering Bees," and "Rearing Queens."

Mr. Geo. Wright was selected to read an essay on "Bee-Keeping."

G. C. GREEN, Sec.

Factoryville, Pa., Feb. 20, 1883.

For the American Bee Journal.

Bee Dysentery Not a New Disease.

S. F. NEWMAN.

In the BEE JOURNAL for Feb. 14, page 95, Mr. Heddon says "he would like to tell S. F. Newman why one of his apiaries has dysentery while the other three have not, all being prepared for winter in the same manner."

Now, Mr. Editor, there are many bee-keepers in Northern Ohio who will be under very many obligations to Mr. Heddon if he will give the desired information, especially if the cause is of such a nature as to be capable of being guarded against in the future, for dysentery is making sad havoc with many apiaries in this section.

I neglected to say in my letter, which appeared on page 26 of the JOURNAL, that our 38 colonies, which have been the worst afflicted, and the most of which have gone where sick bees go, were the strongest, and to all appearance, in the best condition of any we had to withstand a hard winter. Most of them had young queens, and all had brood in from two to five combs as late as the last of October.

I had supposed that dysentery was comparatively a late disease, but I find, in reading one of Virgil's poems, that he had a knowledge of it, and prescribed remedies. I send you the translation of part of the poem. Virgil says:

"But since life has on bees, too, entailed our misfortunes, if their bodies shall languish with a sore disease, which you may know by undoubted signs; immediately the sick change color, a horrid leanness deforms the countenance; then they carry the bodies of the dead out of their houses, and lead the mournful funeral processions, or clinging together by their feet, hang about the entrance, or loiter all within their houses shut up, both listless through famine, and benumbed with cold.

"Then a hoarse sound is heard, and in drawing hums they buzz, and at times the south wind murmurs through the woods, as the ruffled seas creak hoarsely with refulgent waves—as rapid fire in the pent furnace roars. In this case I would advise to burn gummy odors, and to put honey in, through pipes of reed, kindly inviting and tempting the feeble to their known repast.

"It will be of service to mix with it, the juice of pounded galls and dried roses, or inspissated must, thickened

over a strong fire, or raisins from the Prythian vine, Cecropian thyme and strong smelling centaury. There is also in meadows a flower to which the husbandman has given the name amellus, an herb easy to be found; for from one root it shoots a vast luxuriance of stalks, itself of golden hue, but on the leaves, which are spread thickly around, the purple of the dark violet sheds a gloss.

"The altars of the gods are often decked with plaited wreaths of this flower. Its taste is bitterish in the month. The shepherds gather it in new-shorn valleys, and near the winding streams of Mella. Boil the roots thereof in fragrant wine, and present it as food for the bees in full baskets at their door."

Norwalk, O., Feb. 17, 1883.

For the American Bee Journal.

How to Make Honey Vinegar.

W. Z. HUTCHINSON.

At the Michigan State Convention at Kalamazoo, Mr. Bingham had on exhibition an excellent sample of honey vinegar; and, as he told us how many pounds of beeswax was obtained from a certain amount of washed cappings, it occurred to me that the vinegar was made from the honey that was washed from the cappings. Upon addressing a letter of inquiry to Mr. Bingham, he wrote me a long, kind and instructive letter upon the subject, which, with his permission, I now give to the readers of the BEE JOURNAL. It is as follows:

"The cappings should be put into a dripper and allowed to remain about 24 hours, then put into as much water as you may reasonably expect to sweeten a little sweeter than good new cider, with the cappings that you expect to have. I fill an ordinary whisky-barrel with water, and the honey from the cappings, in extracting 1,000 pounds of honey, usually makes it sweet enough. The cappings are left in the water an hour or two, then skimmed out and put into a strainer to drip dry, which they will do in 10 or 12 hours. The drippings are, of course, saved and put into the barrel.

"This slightly sweetened water soon begins to 'work,' and the scum may be taken off with a wire cloth, or other skimmer, as often as necessary, until nothing rises. This sweetened water passes through all the stages of fermentation, the same as cider, until it reaches the point called vinegar. One year, perhaps less, makes it such vinegar as you saw at Kalamazoo. We have used no other vinegar in our family for 20 years, except a year or two when we first came to Michigan, 14 years ago, when I had no bees.

"There is, probably, no profit in making honey vinegar from good salable honey, but in keeping bees there is often waste honey that is of little value. I know of no manner of getting cappings ready for making into wax that is so convenient and profitable, and the vinegar is known to be pure.

"I keep the barrel covered with a cotton cloth, and there is not much danger of getting the water too sweet. If very sweet, it takes longer to get it to vinegar; but it is better when it does get there. T. F. BINGHAM."

A barrel of excellent vinegar for every 1,000 pounds of honey extracted is certainly worth saving. I know of one bee-keeper who will save that barrel of vinegar, during the coming season.

Rogersville, Mich.

For the American Bee Journal.

N. E. O. and N. W. Pa. Convention.

D. VIDETO.

Our trip to the North-Eastern Ohio and North-Western Pennsylvania Bee-keepers' Convention, held at Andover, O., on Feb. 14-15, was very agreeable, for many reasons.

Programmes, covering the whole ground of bee science, were printed, and circulated through the audience, and, judging from the attention and interest manifested, those present had a desire to know more about bees. When a topic was announced by the President, there was no want of debaters. Among the 60 or 70 present (including some ladies), short and pithy speeches sprang up everywhere.

With all the slashing the dollar-queen breeders took, and the advertisers of new-idea hives, new fixtures and half-pound sections without separators, and wide frames in the brood chamber for surplus, and the Given press, to fasten foundation on wired frames, etc., etc., there was the utmost kindness and good feeling, and earnest desire to compare notes and learn more about the modern apiary.

Pet theories and pet practices were alike criticized, and, while all enjoyed the feast, I am confident that many unlearned, and learned anew to profit by closer study and practice.

The first day was rainy, but, on the second, the storm cloud passed over, and the members of the convention were invited to visit the very attractive apiary of Mr. M. E. Mason, where, to the delight of all, a portion of his bees were making their first cleansing flight. Mr. M. has been using the Root chaff hive, in part, but says he will make no more, although he considers them tolerably good for wintering; the objections being that they are too cumbersome for summer manipulation. The rest of the hives are the Simplicity, packed in chaff; the outer box is made of pine and painted, with tin roof and tight bottom. Chaff cushions are placed directly on the brood frames, also filling the spaces outside of the division boards. Examination showed them to be in excellent condition and it was thought by many that they could endure another month's confinement. One very important feature in Mr. Mason's packing, is, that the hive sets into the box, with about four inches of chaff under the hive. The bee stand is about six or eight inches high, and so made as to give little or no moisture to the packing box. Mr. M. has over sixty

colonies, nearly all of which are pure Italians, reared from imported queens. He says the highest type of the Italian bee is not found in the imported or foreign bred, but that when American born and accustomed to our climate, they exhibit all the desirable qualifications. It is but just to say that he has some splendid bees. This section of country seems admirably adapted to the bee industry. Andover is situated 25 miles south of Ashtabula, on a branch of the Lake Shore Railroad. The country is moderately rolling, largely timbered with hickory, maple, ash and basswood; the soil is heavy and adapted to grazing, with a liberal scattering of white clover.

Mr. M. contemplates moving about one-half of his bees, in the spring, six miles away, to a piece of timber, comprising 600 acres, a large portion of which abounds in basswood.

The time of our meeting sped hurriedly by, and, before our programme was completed, the trains admonished us that we must kick the dust from our feet and depart, and, as Providence would have it, I arrived home on the morning of the 16th, to witness my bees, as they had an all-day, cleansing flight. Examinations, one week previous, had shown my bees to be somewhat uneasy, with abdomens extended and symptoms of dysentery about the entrances, with occasional spots on the combs. The warm day of the 16th was a God-send to my pets.

North-East, Pa.

For the American Bee Journal.

Section Racks for Comb Honey.

T. E. TURNER.

This is a subject of much importance, at the present time, to many bee-keepers, and especially to those who contemplate changing from broad frames to some other arrangement for holding sections in place, until they are filled with honey.

There are serious objections to broad frames as section holders. It is with difficulty that the sections, when filled, are removed from them, for the bees fasten them with propolis. The bees often stick propolis on the edges of the sections in broad frames that must be scraped off in order to fit them in the shipping case. When an upper-story or surplus hive is filled with broad frames and sections full of honey, it is hard to take them out without spoiling some of the sections; unless a movable side is used in the upper story, which adds to the expense. That it is easier to make objections to that which is in use, than to propose something better to take its place, is sometimes true, but not in the present case, as viewed by the writer. At the Northwestern Convention, some were desirous of changing from broad frames as supers, if they only knew of something to use that was better. It is important for all who are beginning bee-keeping, as well as for those who contemplate changing from broad frames to section racks, to know which is the best to use, for changing racks, after commencing their use, is costly.

I have used broad frames in upper stories, and at the sides of the brood chamber and section racks, in the same apiary for some years, and I consider the racks about as far superior to broad frames as frame hives are to box hives. I have no interest in the manufacture or sale of any rack, for I purchase my apianian supplies ready-made, but the Hodgson Rack, that was illustrated and described on page 96 of the BEE JOURNAL, for Feb. 14, has been used by the bee-keepers in this locality for four years, and possesses practical merit. As it is public property, any one can make it who desires to do so. This rack is regarded by those who have used it here, less objectionable than an upper-story super, with broad frames, but perhaps some of the greater lights in the bee world will find objections to it, that we lesser lights have not discovered. It does not need to be turned bottom side up, and the sections knocked out, with a jar, as with some others, but by removing the V-shaped beveled wedges and the sides, any or all of the sections can be removed without jarring or danger of breaking the combs. The expense of making it is about the same as half-story super, with 7 broad frames. The observing glass allows the sections to be seen when on the hive, without disturbing the bees, but it can be made with less cost without glass, if desired; and it will admit of tiering up. There is a little board to shut off the bees from a part of the section space to concentrate the bees on partially filled sections, in case the honey flow slackens up. It can be used on top for chaff-packing, just as well as any other, if desired, and has no cross pieces to interfere with packing. With it there is no need of separators. I have used separators on broad frames, but none on the rack, and the sections are about as straight for packing in shipping cases in the one as in the other. Separators can be used with it, if desired.

If this imperfect description of section racks will aid some progressive apiarist to greater success in his "sweet pursuit," my object will be accomplished.

Sussex, Wis.

For the American Bee Journal.

The Adoption of a Standard Frame.

H. D. EDWARDS.

On page 21 of the BEE JOURNAL, for Jan. 10, is an article by J. B. Mason, advocating the adoption of a standard frame. The writer does not tell us why we should throw away our present frames and adopt one of a different size. The advantages he omitted to state; they are so few, and the difficulties so many, that the day is very distant when we shall see the same sized frame used by all the bee-keepers of the country. The inconvenience occasioned by the different sized frames, is easily overcome, by transferring to the one you are using. He admits that some of our most successful bee-keepers are using different

sized frames, according to his particular notions of the size and shape required; and as it has not been demonstrated that a frame of any particular size is any better than a frame of some other size, it will be very difficult to get men to discard the frame and hive they are using for one of a different size, thereby incurring an outlay of time and money, for which they are to receive no adequate return. Locality, the manner of wintering bees, and the production of comb or extracted honey, will always have an influence in determining the size and shape of the frame used. In the extreme Northern States, where bees are wintered on their summer stands, it is generally conceded that a deep frame is best; while a shallow frame, having the advantages for the production of comb honey, is the one most likely to be adopted in the South, where there is no danger from cold in wintering. In the intermediate latitudes, where bees are usually wintered on the summer stands, a frame of medium depth is the one most likely to be selected, as combining more advantages than any other.

I think it a good subject for discussion, in conventions, as it may bring out facts, and help to suggest a frame best adapted to the locality in which members of the convention reside; thereby assisting those who have as yet but few colonies, and those about to engage in the business who are undecided, what frame to adopt.

The Enemies of Bees.

F. THIAVILLE.

In the summer of 1878, when bees were working on mint, cotton and other low brushes, the bee killers were as numerous as the bees, playing destruction. They were also thick in the apiary. I tried to chase them with my net, but with little success.

In this latitude, from the first of May to the middle of June, is the time they are mating; they make a shrill noise and can be heard at 30 paces. Then go around fence corners, and you find them, male and female, hanging to some low bushes, such as sumac and blackberries. They can be caught easily with the hand, and killed. If too high, have your mosquito net and catch them. One day, hunting, in mating time, is sufficient for me, and I am no more troubled with them. We have here 4 varieties, but the most ferocious are the large, black ones, which also catch grasshoppers and other bee killers, in the same manner that they catch bees.

King birds, ants and toads, are little trouble; spiders are more destructive here. Lizards, snakes and scorpions are always hovering about the hives. I have the apiary nice and clean, and keep a good supply of cats and kittens; they catch and eat them. Sometimes scorpions will make cats sick, and, occasionally, kill them.

The bee moth is very troublesome, and puts the bee-keepers on the look-

out, to keep only strong colonies. My bees are mostly hybrids and brown bees; they will not suffer by the moth. I have no pure Italians. Suppose the disease, foul brood, makes its appearance in a country where there is a quantity of wild bees in the forests and rocks, apiarists never will be able to clear their apiaries of it. The bees will constantly bring it back from the forest. I believe the bee moth would be a good agent for destroying these diseased colonies and put an end to it. In a warm climate there is more vermin than in a northern country. We have no winter to kill them.

Bees are doing well for this latitude. Now is the time they make active preparation. Sometimes bees gather considerable honey in March, but April is the general honey harvest here.

Forest City, Ark., Feb. 10, 1883.

For the American Bee Journal.

Preparing Bees for Winter.

H. M. MORRIS.

I cannot say that my bees are wintering extra well. Part of them, at least, seem to be a little "uneasy," crawling out at the entrance when it is too cold for them to fly; most of them get back, however, but they look a little too fat to suit me. They are all packed alike, or nearly so; some have the oil cloths directly over the bees. I have tried some colonies that way, for several winters, and I am convinced that it is a poor plan. This is the way I pack: I put about 6 corn cobs, equally spaced, on the frames, to hold up the quilt so that the bees can pass from one frame to another. I used the cobs long before "Hill's Device" was spoken of, and now I find them preferable to punching holes in the combs, and less expensive than "Hill's Device," and you do not have to store them away through the summer, which is quite an item when you have one or two hundred colonies. Then, over these cobs, I place a good thick quilt, blanket, or old piece of carpet; no oil cloth. Then either loose chaff or a cushion. The object is to have something on top that will take up all the moisture that arises from the bees, and, by the way, I do not call chaff cushions, on top, "upward ventilation." A good thick cushion, that fits the hive so tight that you must crowd to get it in, shuts off "upward ventilation," and that is just what we want. To my mind, upward ventilation is a term synonymous with "Blasted Hopes." Of course, I am speaking now of wintering on summer stands. I say never use an oil cloth next to the bees in winter time. It is too cold; it condenses the breath and makes water form directly over the cluster, and in the end, damp hives, moldy combs and dysenteric bees. What is the good of an absorbent over the bees with an air-tight, water-tight partition between it and the bees? It defeats the one object we are working for. Mr. Doolittle should try it on himself some cold night; crawl under an oil cloth sheet, and you may put

all the quilts you like over you, and you will find yourself wet and uncomfortable, and (unless extra well covered) cold. That fact can be demonstrated by wearing "rubber boots" for any length of time in cold, dry weather. Your feet soon get the dysentery or something else, and you will have a case of spring dwindling that you will remember.

I have wintered from 10 to 50 colonies of bees on the summer stands, in Simplicity hives, through 5 winters, without loss by dysentery or dwindling, and this is my way of fixing them: I crowd them into 7 frames. I know that they have honey enough to last until unpacked in the spring, a thin cushion on either side, then fixed on top as I have described; entrance closed to within an inch; back end of hive 4 inches the highest, so that no water can run in, but all that might gather can run out. Examine each entrance often enough to know that it is not clogged with debris, and if not north of 41°, your bees will come through the winter all right, in nine cases out of ten.

This is the most severe winter we have had since I have paid any particular attention to bee-keeping, and I may lose some; the mercury going to 18° and 20° below. It commenced, last night, with a thunder storm, and we are still having one of the worst ice storms I ever witnessed. Trees look like liberty poles, completely stripped of their limbs. A white birch tree, some 20 feet high, in front of the window where I sit, is bent with its weight of ice, so that its top lies on the ground. Fields are one vast lake of ice; telegraph wires broken down; everything out of doors is grandly beautiful, majestic to look upon, and the damages are also majestic. As I sit here writing I can hear the branches crack and come crashing down to the ground.

Dr. Miller will find my report for 1882 in December *Gleanings*, page 600. N. H. Stewart quotes me, from *Gleanings*, a little wrong. I said: I think bees gather some honey, each year, from corn; his statement is that my bees gather large quantities of corn honey each year. I am not positive of that. I know that they did this year. Corn honey has such a peculiar quality that if one ever gets a yield he will be apt to know it if he ever gets another, and I am quite sure I have had corn honey before.

Rantoul, Ill., Feb. 2, 1883.

For the American Bee Journal.

Marshall County, Iowa, Convention.

The Marshall County, Iowa, Bee-Keepers' Association met in Marshalltown, Iowa, at 1 p. m., on Jan. 6. The minutes of the previous meeting were read and approved. The subject of wintering was then discussed.

Mr. J. Moore stated that his bees wintered in his cellar, prepared on purpose for them. It is dark, and ventilated by flues starting in the cellar. He lost heavily, 2 years ago, but thinks mostly by his own neglect in not keeping the entrances open. He

now keeps the entrances open the full width.

President Barrows said he lost none 2 years ago. Does not darken his cellar; the hives face the wall; flues start from cellar, and when the weather permits he opens doors and windows for ventilation. If cellars are kept near freezing point, they will keep more quiet, and not be liable to come out, if the cellar is a little light.

The secretary read an article from the BEE JOURNAL by G. M. Doolittle, on "Winter Flights."

Mr. Moore said he preferred wintering in the cellar, but should try outdoor wintering, by giving protection, if his numbers still increased. He now has 50 colonies in good condition. All present were much interested, and reported extra returns for the past season, and bees in fine condition for the winter.

The next quarterly meeting will be held on Saturday, March 21, at 10:30 a. m., at the Sheriff's office, Marshalltown, Iowa. Subject for discussion: "Spring and Summer Care." We hope many Iowa bee-keepers will attend the next meeting.

J. W. SANDERS, Sec.

O. B. BARROWS, Pres.

Do Bees Need a Winter Flight?

FAYETTE LEE.

I have kept bees for 6 years, and have let them have 2 flights between January and April, with good results, for the first 3 winters. Every colony coming through in good condition; but during the last 3, they had the dysentery from dampness, and the winter flight did no good. It caused them to try to dry the hive, by sipping up the water that had accumulated on the combs, and in a few days they were worse than ever. I believe that dampness and breeding causes dysentery. About Jan. 28, I went into my cellar and heard a colony making a fuss about something; I raised the cover and looked into the hive; it was full of bees from top to bottom, and the water stood in big drops on the under side of the cover. I took them out and gave them a flight; they had 4 frames of brood. I put them back into the cellar, and before April 15, they were all dead, with plenty of honey. When I put my bees into the cellar, I put a newspaper on top of every hive, to make them air-tight at the top. I learned a lesson, to never stop upward ventilation, because some one said so. The temperature of the cellar was 50° most all winter; bees commenced breeding the last week in January, and made bad work of it. This winter, my cellar stands from 36° to 40°; bees are quiet, and there are no dead bees on the bottom of the cellar. I shall give them no flight this winter. We have had steady cold weather since New Year's day, with some days as cold as 32° below zero, with the worst blizzards I ever saw. Last winter I took up a dust pan full of bees from the cellar bottom and put them beside the stove.

and most of them came to life. That shows me they do not die with old age. One spring, when I put my bees out, I found one colony of Italians that had no brood; the combs were dry and the bees healthy, and I never saw a colony do better, through the summer.

The best cover to put over bees in the cellar, is half-inch basswood, just large enough to cover the hive; it will warp just enough to give good ventilation, and it will take up the dampness. A new cellar is a poor place to winter bees in, unless it has a large ventilator running to the roof. The Syrian bees suit me best for extracted honey, the blacks for comb honey, and the Italians for business. I had one colony of Italians that put all of their honey in the upper story, so I had to feed them in the fall. Honey sells at from 15 to 25 cents per pound here.

My Experience With Sweet Clover.

JOHN H. MARTIN.

Several weeks ago, Dr. Miller requested me (by postal card) to give my experience in the sowing of sweet clover, referring to my article upon bee farming, on page 308, BEE JOURNAL for 1881. It is very easy for us to give our plans and directions for sowing or planting our crops, but the result, at the close of the season, is sometimes a heart-sick task.

My experience, then, with sweet clover, is this: About 5 miles from my apiary the roadside is full of sweet clover. In the fall of 1880 I gathered enough seed to sow an acre. It was sown upon gravelly loam. As the books all say sweet clover will grow anywhere, even upon a rock, I did not spend much time in preparing the land by manuring, but gave it a thorough harrowing. At the proper time for plants to be coming forth, you would have frequently seen a bee-keeper about my size prospecting that acre of ground for sweet clover. I prospected, from time to time, during the whole season, and at harvest time I could have easily carried the crop, honey, blossoms, fodder and roots, all in one hand; it was a complete failure. A portion of the land was quite rich and moist; upon this a few diminutive straggling plants put in an appearance.

I have the same experience in sowing upon the roadside. It will not catch permanently. If, now and then, a plant does mature and casts its seeds, you will find none there the next season. The species of clover I have experimented with is *an annual*. It seems to thrive best upon clay soil. I hope to give it another trial upon a field of clay with plenty of manure, another season. The idea that, because it grows upon the roadside, it is growing upon poor land is a mistaken one. Our highways, and especially all of the land between the fences here in the Eastern States, is the richest land we have. The scrapings in the hol-

lows and ditches is nearly equal to barnyard manure. There is evidently great value in sweet clover blossoms, for during the past season, when our apiary was yielding no honey, those having bees within reach of sweet clover received much benefit from that source. The question with me is, how to sow it, so as to have a good reliable growth. I have thus far followed nature's plan, have sown in the fall, perhaps I should sow in the spring.

I find the Simpson honey plant, or figwort also, hard to start from the seed, but this objection can be overcome, by starting plants in a hot bed, and transplanting them. By this method, arapid and successful growth is secured, and although I have had but a few plants in my yard, I think it the best plant, exclusively for honey, I have yet seen. It comes to maturity the second year, and our plants were fully 10 feet in height, and had half a dozen or more stalks, all full of blossoms; and the beauty of this plant is the seemingly unceasing flow of honey. The bees were at work upon it in myriads, from early morn until dewy evening, in rainy weather or in time of drouth. It was the "old faithful," among our honey plants. I hope to set an acre of this plant this spring. I also consider alsike clover a bonanza for the bee-keeper, even if he owns not an acre of land, his farming neighbors can be induced to sow it for their stock.

Hartford, N. Y.

[This is about the only failure in propagating sweet clover, we remember of seeing recorded, and we fully believe that there is some mistake about it—either the seed was poor, the land too rich, or some climatic difficulty prevented its development. It is best adapted for poor clay, but will certainly grow and thrive in some good land, as we have proved, year after year. Probably the key to this failure is found in the *third* paragraph, where Mr. Martin says: "The species of clover I have experimented with is an *annual*." *Melilotus alba* (sweet clover) is a biennial, and not an annual, and hence it *must have been another plant entirely*.—ED.]

For the American Bee Journal.

Are Sections Under 1 lb. Profitable?

F. I. SAGE.

I notice by the BEE JOURNAL that the impression seems to be gaining ground among bee-keepers that it is more desirable and profitable to have comb honey put in half-pound packages. Having bought of the producers, during the past season, upwards of 50 tons of comb honey, perhaps they may think my views on the subject worthy of notice. Permit me to say (and most emphatically) that I am not in favor of using the half-pound sections, and never advocated

the using of them so small as one-pound. Certainly, we want nothing smaller than the pounds. It may be said that I am selfish in this matter, and I admit I am to this extent, viz.: That I believe I can sell more pounds or tons of honey by handling nothing smaller than 1½ or 2-pound sections, than I can if handling 1 or ½ pounds.

What is for my interest, I think is also for the interest of the producer, and the merchants with whom I deal. To illustrate: A buys 5 cases of honey, in 2 pound sections; to sell this, he makes 60 sales; B buys 5 cases, containing 24 one-pound sections; he must make 120 sales; C buys 5 cases, containing 240 half-pounds, and, of course, must make 240 sales. Which one, do you think, will first sell his stock of honey? Having tested the matter thoroughly, I know the 60 two-pound sections will be sold long before the 240 half-pounds. I know it is said the pounds and half-pounds will be sold to many who would not buy the larger size, but you must remember that there are many who would buy the pounds who would just as soon take the two-pounds, if nothing smaller was at hand. I deal with many who will not buy so small as the one-pound package of honey, and would laugh at the half-pounds, considering them only as novelties. They would say, at once, when the honey trade comes to this, we want no more of it. Suppose I handle 50 tons yearly of two-pound packages; 40 tons of one-pounds, or 30 tons of half-pounds would supply this same trade. This, I firmly believe. It is said Boston pays 5 cents per pound more for half-pound sections. For the sake of the argument, we will admit she has, for a very limited quantity, but why did she do it? Simply because it was a novelty! I happen to know that Boston has been offered half-pound sections for much less than quotations, but she would not buy them for cash, at such prices.

If it is for the interest of the merchants, and for mine, to handle nothing smaller than 1½ or 2-pound sections, is it not also for the interest of the bee-keeper to use sections of that size, and not strive to cut his own throat by coming down to the "penny package?" Of course, if he understands his business, he knows he cannot produce a given weight of honey in penny packages for the same price, per pound, that he can in 1½ or 2-pound sections. If he feels as though he was getting rich too fast, and his conscience troubles him much, let him sell his large packages for the same amount of money that his honey crop would have brought him, had it been in half-pound sections. Let me illustrate how this penny package business works: I have a trade that has never, until recently, used anything smaller than two-pound sections; along comes a man who has one-pound sections; they look nice, are a novelty, and a little persuasion on the part of the seller, induces the merchant to try a case, which takes the place of 2 cases of two-pound sections. Next season along comes the half-pound sections, and he again buys, which again re-

duces his sales, but the worst of it is, that after these small packages have been introduced, the people seem to think they want them, and if they cannot get them, quite likely they will take none, and the merchant begins to think the honey trade is scarcely worth bothering with. In fact, I know of a number who have given the honey trade the "go by" altogether, during the present season.

Again (you may laugh at the idea, nevertheless it is a fact), that there are thousands of otherwise intelligent people, who firmly believe that all these small nice cakes of honey are manufactured by man, and will not believe that bees can be trained to do such work. I claim it is for the interests of the bee-keeper, the merchant and myself, that nothing smaller than two-pound sections are used, and will try and show how a few bee-keepers can force the many to work at a loss to all concerned. For instance, a bee-keeper in a certain locality uses a few one-pound sections, perhaps gets $\frac{3}{4}$ as much honey as he would by using two-pound sections, but gets 1 or 2 cents more, per pound, for his honey. He introduces the small packages; they are liked and called for, thus forcing the dealer to buy what his customers ask for. Next season he cuts to the half-pound size, and perhaps gets $\frac{1}{2}$ or $\frac{3}{4}$ as much as in pounds, but gets a trifle more per pound after the small size is established, all must come to it, and the bee-keeper gets no more per pound for his honey than if all were in two-pound sections. Then again, how soon will we get to 14 pound and "penny packages." When that time arrives, will be a good time for cash honey buyers to buy a peanut stand. Time was, when the 4-pound box sold for more per pound, glass and all, than the half-pound novelty will ever bring. Since September I have had a standing order for 1 or 2 tons of honey in 4 and 6-pound packages, but in my travels of several thousands miles, I have not been able to find 100 pounds of such size boxes. How has this change been brought about? Simply by the bee-keepers themselves. A few enthusiasts, who want to go a little beyond others, cut the size of box or sections, and in the end all are obliged to adopt that size, and sell their $\frac{1}{2}$ or $\frac{3}{4}$ crop of honey at the same price, per pound, that it would have brought in large sections, if none had started the use of smaller size boxes.

I believe bee-keepers earn every dollar they get, and think those who adopt the half-pound sections, will be obliged to earn two for every one received, beside doing a damage to all other bee-keepers. At the rate we are progressing now, we will soon have "the penny package," and then will have to throw in a chromo for each sold. My advice to the bee-keepers is never to use anything smaller than the one-pound sections, and think, if that had never been used, it would not now be called for. I am surprised that so level a headed man as Mr. Heddon, could see anything so small as a half-pound cake of honey.

Wethersfield, Conn.

For the American Bee Journal.

Separators of Wood.

W. D. WRIGHT.

On page 58 of the BEE JOURNAL, F. H. Finch, under the above caption, says: "Now I claim to be the first person in this country that adopted the wood separator, which I did five years ago." If Mr. Finch wishes to sustain his claim of priority in the use of wood separators, he will have to go back several years further. They were used by at least one man in this section in 1867 (some one may have used them even prior to that date, I cannot say); he used them between small frames for surplus, and I used them in the same connection in 1869. In 1876, I used them between two-comb or 4-lb. boxes, in both top and side storing, placing 4 boxes in a row, and glassing the sides after they were filled.

In 1877, I used them with 2-lb. sections, and, in 1879 and since, I have used both wood and tin separators extensively, and have been successful with both, but, for several reasons, I prefer the wood. I have not experienced any of the difficulties mentioned by Mr. Gould and others. I believe that I can obtain just as much surplus honey with the use of separators, as without them.

In 1881, I obtained an average of 100 lbs. comb honey per colony, spring count. I have not had one comb in 500 attached to the separators, unless the foundation had fallen down. I could not entertain the idea of securing a crop of comb honey in marketable shape, without the use of separators of some sort.

In reducing the size of our section boxes, there is certainly a limit beyond which we cannot go, and still make them as profitable to the producer as larger packages, and I believe the advocates of the half-pound section have gone beyond that limit.

Mr. Heddon thinks extra cost and manipulation the main objection to their use. Allowing these to be the only objections (which I think is not the case), I believe there are good and sufficient reasons for their general non-adoption, as both of these items would be increased about fourfold over the 2-lb. section. The item of manipulation may not amount to so much with Mr. Heddon, for he gets his help cheap, but to a person who pays for extra labor it is no small item.

Mr. F. C. Benedict, who has had several years' practical experience with these small sections, tells us in his able article, that he can produce one-third more honey in pound than half-pound sections, and double the quantity in two-pound sections, while Mr. Heddon, whom we are led to believe has had no practical experience with the half-pound sections, is ready to convince Mr. Benedict that more comb honey can be procured in pound or half-pound sections than in any larger receptacle. Shall we base our calculations on theory or practice in so important a matter?

The present market quotations on honey in half-pound section is high, but, doubtless, cannot be maintained when a large quantity is placed upon the market.

Some say that we must cater to the wants of consumers, but I doubt that they ever made so unreasonable a demand as a half-pound section of comb honey. The demand has been created by the producers themselves.

The two-pound section suits both me and my market, and I shall continue its use, let others do as they may. Knowersville, N. Y.

Convention Notices.

The Union Bee-Keepers' Association will meet in Grauge Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.

Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nello's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

The Eastern Michigan Bee-Keepers' Society, will hold its annual meeting in Detroit, April 3, in Abstract Hall, commencing at 10 a. m. An interesting meeting is expected, and bee-keepers are requested to send items or questions of interest to the secretary in time, that they may be announced previous to the meeting.

A. B. WEED, Sec.

75 Bagge St., Detroit, Mich.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address; Essays: Prof. A. J. Cook, on Wintering Bees; S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. Wood, Sec.

North Lansing, Mich.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

New Catalogues and Price Lists.

We have received the following new Catalogues and Price Lists of Bees, Queens or Apiarian Supplies:

James Heddon, Dowagiac, Mich.
Bright Bros., Mazeppa, Minn.
A. D. Benham, Olivet, Mich.
W. S. Cauthen, Pleasant Hill, S. C.
F. A. Snell, Milledgeville, Ill.
E. Kretschmer, Coburg, Iowa.
J. P. Moore, Morgan, Ky.
H. H. Brown, Light Street, Pa.
E. J. Baxter, Nauvoo, Ill.

SEED CATALOGUES.

Edward Gillett, Southwick, Mass.
G. L. Miller, Jones Station, O.
Jos. Gilbert, Palmyra, N. Y.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., March 12, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—Extracted, dark 7c. light, 8c. here.
BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, on arrival; dark and off-colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@8c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival.

BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@14c. Extracted, 8c. to 10c., according to color.

BEESWAX—32@33c. per lb. for good.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Aside from small lots, off in quality, there is none offering. For the descriptions now in market there is virtually no demand.
White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9@9c.; dark and candied, 5@7@7c.

BEESWAX—We quote 30@33c.
STEARNS & SMITH, 433 Front Street

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16.—some inferior sold at 10c.; strained at 6@7c., extracted at 7@8@8c. lots in small packages more.
BEESWAX—Choice and wanted at 32@33c.
W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 19@20c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 10@10c. in bbls. and 11@13c. in cans.
BEESWAX—Scarce, 28@30c.
A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—The prospect is very poor for selling honey in this market. I think there is all the honey here that will sell this season, unless it sells faster during the next month than it has this.
BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly.
Western pure, 30@32c.; southern, pure, 31@33c.
D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX—Our supply is gone; we have none to quote.
CROCKER & BLAKE, 37 Chatbam Street.

Mr. W. S. Cauthen, Pleasant Hill, S. C., has sent us one of his improved queen-cages. The improvement consists in the box to hold the candy, and keep it from soiling the mails. It is similar to the Peet cage in other ways, but has a wood slide instead of a tin; this is an improvement, wood being not so cold as tin.

DO NOT FORGET to send for Moore's new price list of Italian queens, nuclei and full colonies. 3-frame nucleus and tested queen, \$5.00.
Address J. P. MOORE, Morgan, Pendleton co., Ky.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

FOR SALE CHEAP!

I have 25 to 50 colonies of Italians, hybrid and Arkansas brown bees, in A 1 condition, with plenty of stores and brood, which I will sell, on the landing, at \$3.00 per colony. Address

G. B. PETERS,
Council Bend, Ark.

(ESTABLISHED 1864.)

BEE-SUPPLIES.

We furnish EVERYTHING needed in the Apiary, of practical construction and at the lowest price. Satisfaction guaranteed.

Send your address on a postal card and we will send you, free, our large, illustrated catalogue.

E. KRETCHMER, Coburg, Iowa.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

"Friendly" Law Suit.

The BEE JOURNAL has always defended *honest* property in inventions as well as in anything else. For the first seven years of its existence, under the able management of our predecessor, the late Mr. Samuel Wagner, it deprecated the war made on our venerable friend, the Rev. L. L. Langstroth, and his patent, and the consequent annoyance and continual appeal to the courts to defend that patent. His present dependent and helpless condition, is mainly attributable to the *war* that was made on him, and it is surpassingly strange that some who know all this, now talk of waging a similar war on another inventor.

On page 127, Dr. Southwick gave his views of the subject, and now Prof. Cook sends us the following:

KIND REJOINDER TO DR. SOUTHWICK.

I am quite sure that my good friend, Dr. E. B. Southwick, and I, do not understand matters alike. He says he is not a Christian. Now, did he understand Christianity as I do, I am sure he would say, that whatever I am, I *desire* to be a true, genuine Christian. Which means: I desire to follow Christ's example. He "went about doing good." In his life was no guile. His were the noble words: "Let him that is without sin, cast the first stone;" and that grandest prayer: "Father forgive them, they know not what they do." Now, my dear doctor, do not you and I desire to copy all this? One thing more: Christ only had words of sharp condemnation for impostors. Now, I have feared—I almost believe that in this one-piece section business, the impostor shows his face. If I felt that Mr. Fornerook had studied, labored and spent money to develop the one-

piece section, and so had *honest* property in it, I would rival my good friend, Dr. S., in my vehement demands, that he have his rights. But if, as I surely believe, we would have had the section just as soon if Mr. F. had never been born, and that his claim to invention is not a just one, then, surely, the case is very different. I believe Mr. Muth, because he invented the wire comb basket with inclined sides, has just as good a right to forbid all parties to make and sell extractors, as has Mr. F. to forbid the manufacture of one-piece sections, as he does.

Nay, my friend, there is a principle at stake right here. Let us uphold every true inventor's right to *his own* invention. Let us *denounce* as slothly the collecting of royalty by threats of prosecution, where no right exists. You speak of 25 cents royalty. Why, Doctor! it is two dollars.

It may not be wise to have the friendly suit. I am, however, quite sure that all the apiarists, who use sections of this kind—and they are *very numerous*—could well afford to pay the \$1.00, if the alternative was to buy at the higher price.

Of course, this whole question hinges on Mr. F.'s right. If, as I believe, his right is a fictitious one, then "right," which you, Doctor, are proud to worship, demands that his claims be opposed. Such action does not apply to this case only, but to all such cases which are sure to arise in the future. I am now done.

A. J. COOK.

Lansing, Mich., March 9, 1883.

Of course, we are sorry that Professor Cook (who is, naturally, a very fair-minded and honorable man) has seen fit to use such strong language as *impostor*. It is not like him; and, we fear, he labored under some impulse or unnatural influence.

Here comes another—from Mr. J. Lee Anderson, who desires to be heard:

It seems to me that Dr. Southwick on page 127, has taken the most honest position of any one, as yet, in the patent one-piece section. Prof. Cook suggests that each bee-keeper put in one dollar and have a "friendly" law suit with Mr. Fornerook.

I would suggest that bee-keepers put in another dollar, each, to give Mr. Fornerook, with which to defend

the "friendly" suit. I think all that are *honest* in their friendship will do so; for, if Mr. F. owns the patent it certainly would be very wrong for bee-keepers to combine together to beat him out of his rights, thereby putting him to great expense and a large "section" of trouble.

J. LEE ANDERSON.

Lawrence, Ill., March 9, 1883.

Mr. Anderson is right. If the patentee did invent the section, and spend much time and money to develop and make it a success, may we not as *honestly* appropriate his pocket-book to our use, without his permission, as to combine to *beat* him out of his interest in it! If it is to be tried *legally*, and bee-keepers desire to have a thorough investigation of the legality of the patent, they should aid one side as much as the other—that is, if they desire to be equally *honest* and *just* to the inventor and to the fraternity.

We have declined to publish replies sent by Mr. Baldridge, because they contained such ungentlemanly and untruthful words and expressions as the following:

The article is a gross libel, full of lies, and you ought to know it.... You misrepresent for selfish ends.... Brace up, and publish my article just as it is written, and not append remarks thereto.... Coward.... Why, the devil, don't he try to stop somebody from making them?... You are *advising* bee-keepers to raise a fund to test the validity of the patent, and fee the lawyers (liars) with.... Cool off.... Publish this....—'s article is "chock full of lies.".... Some have written me that you are now interested in the F. patent, and you aided him with solid cash, in getting the patent.... If you have "stock" in the F. patent, take my advice and unload, before the bee-keepers "smell a rat."

Had the replies been courteous they would have been published, but *no good* can come of such bitterness and strife. We feel *sure* that our readers generally will approve of the controversy being terminated right here.

We have no interest in any patent, or in the manufacture or sale of any apiarian supplies; nor have we ever assisted any one with money to get a patent. The spiteful intimation to the contrary is without the slightest foundation, and was begotten out of malice and ill-will.

Bee-Keeping as a Specialty.

G. M. DOOLITTLE.

I was very much pleased with Dr. Miller's article, "Who Shall Keep Bees?" on page 36 of the BEE JOURNAL, and also with one given on page 10 of the *Bee-Keepers' Exchange*, which was read before the N. J. B. K. Association; title, "Too Many Eggs in Our Basket." Both of these articles give the opposite side of bee-culture from what is generally presented, and is just what is needed to guard the beginner against going recklessly into bee-keeping, by putting his last dollar into a business he knows nothing of. It is this getting crazy over a business which looks to be a good thing, but with which we are not acquainted, and investing all we have in it, expecting to make a fortune, which ruins so many. To be successful in anything, a man must "grow up" into it, by years of patient toil and study, till he becomes master of the business, when in 99 cases out of 100 he will succeed. I was brought up a farmer, and educated by my father as such, so that, were I to change my occupation at any time, it would be to that of farming, unless I could have time to study up some business better to my liking, before I left bee-keeping. In the winter of 1888-89 I became interested in bees, by reading the first edition of King's bee-keepers' text book, which chanced to fall into my hands. Next I subscribed for the BEE JOURNAL, read Quinby's and Langstroth's books, and in March bought two colonies of bees, and the hives I needed for two years, paying \$30. 1889 being a poor year, I had but one swarm from the two, and had to feed \$5 worth of sugar to get them through the winter. In 1870 I received enough from them to buy all the fixtures I wished for 1871, and a little to help on my other expenses from the farm. So I kept on making the bees pay their way, as I had resolved, at the outset, that after paying the first \$35 I would lay out no more money on them than they brought in, believing that if I could not make two colonies pay, I could not 200. In the fall of 1873 I found I had an average yield of 80 pounds of comb honey from each colony I had in the spring, which was sold so as to give me \$550 free of all expense incurred by the bees. I also bought an extractor that season. As I was determined to give my bees the care they needed, and knowing that the time the bees needed the most attention came in haying time, I hired a man to take my place in the hay-field. It so happened that he commenced work on the day basswood opened. Previously I had hived a single swarm in an empty hive, and concluded to devote them to extracted honey. The man worked 16 days at

\$1.75 per day, and I extracted, during those 16 days, honey enough from this swarm to pay the man for his work. I state this to show that one new swarm of bees was equivalent to myself in the hay-field for 16 days, yet how many keeping 30 to 50 colonies of bees leave them to go into the hay or harvest field, and then tell us bee-keeping does not pay. You can hire a man to take your place in the field, but if you expect to become master of the bee business, so as to make it pay, you cannot hire a man to take your place in the apiary during the honey season. But to return: In 1871 my honey was sold so as to bring \$970 free of all expense. At this time I began to think of giving up the farm, but finally concluded to hold on to it one year more, to make sure that I could make bee-keeping pay as a specialty. After deducting the expense of the bees from the sales, I found that I had the next year (1875) the amount of \$1,431, and hesitated no longer, but gave up farming and embarked in the bee business, with nothing else as a source of revenue.

As it may be interesting to know how I have succeeded since then, I will carry the report up to the present time. In 1876 my net income from the bees was \$774; in 1877, \$2,266; in 1878, \$772; in 1879, \$537; in 1880, \$781; in 1881, \$1,078; 1882, \$822; making a total of \$9,300 during the past 10 years. The average number of colonies in the spring of each year, worked to produce this result, was about 48. Had it not been for existing circumstances which required my keeping so limited a number of colonies, I believe I could have taken care of 100 colonies (spring count), and secured nearly double the amount.

In the above showing all expenses have been deducted except my time, which you will see gives a salary of \$999 a year, as will be accorded by all. But what about the first four years during which I was experimenting, reading and thinking about bees all my wakeful hours, many of them hours when I ought to have been asleep, giving the subject as much or more study than any lawyer ever spent on his profession. To be sure the bees paid their way, but to what shall I look for my pay? To be just I must divide my \$9,900 by 14 years, which gives me about \$714 a year as the real pay I have received for my labor. Is this enough pay for the labor performed? Well, many would not be satisfied with it, and multitudes would be glad to get such a salary. P. H. Elwood (one of the largest honey-producers of our State, though never heard from of late years) once said to me, "that a man who was capable of successfully managing 100 colonies of bees would command \$1,000 salary a year in any business." If we accept this statement as a fact, then, like Dr. Miller, I can say, "I should be better off in this world's goods if I had never kept bees." But when I turn my eyes to the thousands who do not get one-half \$714 a year, working in factories, in the shop, on the farm, and doing drudgery of all kinds and descriptions,

I turn my eyes back with pleasure to our fascinating and health-giving pursuit (bee-keeping), and say: It is enough; I am satisfied.

My advice to all thinking of bee-keeping as a business, would be, get one or two colonies of bees; post yourself by reading of and experimenting with them, as you can find time to do so from the business you are already in, and thus find out for yourself which is the better for a livelihood, the business you are already in, or keeping bees. If successful after a series of years, you can be able to take bee-keeping as a specialty, and not be obliged to exclaim with the writer of the article in the *Exchange*, "Too Many Eggs in One Basket."

Borodino, N. Y.

For the American Bee Journal.

Will Freezing Eradicate Foul Brood?

D. A. JONES.

In reply to Mr. O. E. Burden's query, on page 134, as to whether freezing will eradicate foul brood, I would say that I am quite satisfied that freezing will *not* kill the germs; honey subjected to a temperature of from 20° to 35° below zero will not kill the germs. When fed to a nucleus, the following spring, frozen honey gave them the disease. Combs subjected to the same test and temperature were not freed. I do not believe that a tin of "foul-broody" honey, kept frozen in a solid cake of ice in the Arctic regions for five years, would be cured of the disease; nor do I believe that combs can be cleaned by subjecting them to a temperature of from 40° to 60° below zero. I most certainly should advise all to render the combs into wax, boil the honey and scald the hives and frames. You only lose your own time, which will not amount to more than one hour to each colony. The cost of making up the wax into foundation, should not be more than 10 cents per pound and the freight each way.

Beeton, Ont., March 10, 1883.

For the American Bee Journal.

Small Sections, Honey, Eggs, Etc.

DR. J. R. BAKER.

In my last communication to the BEE JOURNAL, I referred to James Heddon as one of the apiarists who advised caution in the adopting of the half-pound sections; but I see in a later article in the JOURNAL that he intends to use the Lilliputian affairs quite extensively, so I must have been mistaken as to what he said on the subject previously. Still, I am of the opinion that the safer plan will be for the majority of honey-producers to be slow in adopting so small a section. I think a reaction will set in before many years in this matter. At all events, I believe the better way is to make the change gradually, and feel our way as we go. Experience is the best test for all untried theories; but it is not always safe to experiment very extensively in the outset.

Mr. Heddon thinks that I err in calling the cross-bred bees "irascible insects." My experience has not been so extensive as that of Mr. Heddon; but, with me, the bees that show from one to two yellow bands have always done the best work for me in the way of gathering honey, and have also proved themselves more nervous and ill-humored. That my experience should prove an infallible guide, I do not claim.

My handsomest, yellow bees have invariably been my laziest, as well as most docile ones; but as I said in the BEE JOURNAL of Jan. 31, I am inclined to the opinion that if careful breeders would select the very best yellow bees to breed from, and without "variableness or shadow of turning," behead every queen whose bees proved to be indifferent workers, that there could be a magnificent strain of golden Italians produced. Let it be well understood that, no difference how pretty a queen may be, or how many well defined, yellow bands every one of her progeny may show, unless they are good workers in the field, the queen should be superseded at once.

Dr. I. P. Wilson, of Burlington, Iowa, has some very handsome yellow bees, and some excellent workers. I asked the doctor where he got his strain, and he said it was a cross of several strains; or, to be more explicit, he got Italians from several good breeders, and bred his strain out of the combination. To my mind this tells the whole story. I have no wish to be dogmatical, but I believe I am right in my conclusions; further experience will tell. The bees in my apiary, last season, were the outgrowth, largely, of a cross between Italians from Dadant & Son and Henry Alley, and native blacks. From 19 colonies, spring count, I increased to 43 colonies, by natural swarming, and 5 swarms went to the woods, because of my absence from the apiary at the time of their swarming. From this little apiary I harvested 2,000 pounds of nice comb honey and 600 pounds of excellent extracted, and this, too, without the use of any comb foundation, except small starters in a portion of the sections.

But cannot just as good a record be made with a well-bred strain of Italians? I mean, bees that are beautifully marked with three yellow bands, and as gentle to handle as the more lazy beauties with which I have had some experience. I purpose getting some of the best Italian queens, the coming spring, from different breeders, and breed them into a strain of my own, and see what the ultimate result will be.

Mr. Heddon thinks that my advice, or my prescription of honey, eggs, milk and blackberries not a good one. I did not make the suggestion for men like Mr. Heddon, who have opportunity and ability to make honey-production, alone, a paying business. But there are thousands of people who cannot do as Mr. Heddon and a few others have done, and are still doing. People must be governed by their circumstances, and while but comparatively few can do as Mr.

Heddon does, there are thousands who might procure a few acres of land and raise some small fruit, cultivate a vegetable garden, keep a hundred hens, and a good cow or two, and cap the climax by having a small, well-conducted apiary. If the products of this combination would not tickle the palate of an epicurean, he would be hard to please; so it seems to me. Any man or woman who has common-sense can take a good Manual, like that of Prof. Cook and the BEE JOURNAL as guides, and make a success of bee-keeping on a small scale; if not prepared, or disposed, to go into the business exclusively. The course I have suggested may not make people rich, but it will make them happier than if they were rich, that is, if you call money hoarding, riches.

If all persons, who keep bees, should make it so large a business as does Messrs. Heddon, Doolittle, Scudder, Miller, and a few others, the best comb honey, in my opinion, would not bring 5 cents a pound in the best markets.

Keithsburg, Ill.

For the American Bee Journal.

"Was That Bad Advice?"

JAMES HEDDON.

Yes, doctor. We still consider your admonition to "set a rack of thin sections down on the brood frames, as the worst kind of advice. You are surprised, however, that I should call such manipulation a violation of the instincts of the bees. In the way in which I mean "violation," I will try to show you that it is. Some 5 or 6 years ago I got the idea that I could make top bars to movable frames answer the double purpose of top bars and honey-board. I made them thick and just wide enough to leave a $\frac{5}{8}$ space between them; these made the narrow, bottom piece of my section the same width, and arranged the rack to hold sections in such a way that they would rest directly on the top bar, which came flush with the top of the hive. It seems to me that all will readily guess the solidity with which the sections will be glued to these bars and the difficulty of removing them. I found, when putting this system into practice, that the bees took to the honey boxes no more readily than when they pass through a honey-board and two shallow air-chambers. I found I had been "straining at a gnat," and had now, either to "swallow a camel," or throw away this experiment. Of course, I threw it away.

When I began bee-keeping, I lost so much by following bad advice, coming from those who wrote up a big thing before they had thoroughly tested it, I decided that I would not advise the use of methods that I did not know to be best by actual experience. Hence, I passed this experiment into oblivion, from whence I never should have called upon it, but for the very bad advice given by the doctor. With the case or super method, more especially with the honey-board between the upper and lower stories, there will be

no bits of comb or glue connecting the sections with the lower story of the hive; the case will lift off easily and clean. While there are most serious objections to the sections touching the frames below, I see no advantage unless it be to make it more difficult for thieves to steal your surplus honey. Let "several apiarists of large experience" assure us of what they please, is there one such apiarist who now adjusts his sections as advised by the doctor? If so, let us "chip in" and send a missionary to visit him.

The doctor infers that his impractical method is almost a necessity to the half-pound sections. Why, I cannot conceive. I can make bees work just as fast in half-pound sections as in two-pound sections. The facts are these: A worker bee is a small animal which can readily pass through a space 5-32 of an inch. She is ever ready, when in the least crowded for room, to occupy the 5-16 spaces above the frames with a cell here and there in which to place her nectar, and yet many suppose she is going to bump her elbows in half-pound sections. It seems to me she has more room to turn around in a row of eight half-pound sections than in a one-pound section, whose either side is lined with tin separators.

Allow me to thank Mr. C. R. Isham for his nice samples of wood separators, as well as his concise replies to my queries. I shall not only put the samples he sent me into "practical experiment," but likewise a whole box from the same source.

F. C. Benedict, on page 117, strikes right out on the shoulder, and hits us non-separator men a pretty hard blow. I like him for it. His article carries with it evidence of earnestness (that's twin brother to honesty, you know) and experience. He says that no one can manipulate 100 colonies for comb honey, and produce it in first-class marketable order without the use of separators of some kind. Regarding the first part of his proposition, I will say, that with my case-method, without separators, I can manipulate far more colonies, and with greater comfort, than can be done with any system with which separators are used. Whether the honey is in first-class marketable order, the question will arise, what is "first-class?" I get the combs so straight that nearly all producers and honey merchants think I must have used separators. More than 2-5ths of my combs will glass. None touch each other in the cases. I see no more danger of leakage or breakage than with combs stored between separators. Of course, not *all* the combs are as smooth and straight as those built with separators. I wish they were, but is the difference great enough to pay me for using separators?

The experiments I made some years ago, pointed to my assistants and myself, the fact that we lost honey by the use of separators. We may have been mistaken. Mr. Benedict's sentence, "I know of what I speak," has weight with me, and strengthens my determination to put this matter to an extensive and undoubted test the coming season. What Mr. Benedict

says about thick and thin combs, I think nearly correct. There is a point in the thickness of combs, or in the distance given to the bees in which to build combs, at which we will get most easily the straightest and best combs, and that point reached we will also find that with said thickness we shall get our combs built, filled and sealed quickest as well as straightest. Upon this point I have experimented considerably, and I believe, and shall adopt $1\frac{1}{2}$ inches without and $1\frac{1}{4}$ scant, with separators. Taken all in all, I feel thankful to Mr. Benedict for his vigorous article.

Dowagiac, Mich., March 3, 1882.

For the American Bee Journal.

N. E. Ohio & N. W. Pa. Convention.

The fourth annual convention of the Northeastern Ohio & Northwestern Pennsylvania Bee-Keepers' Association was held in Andover, Ohio, Wednesday and Thursday, Feb. 14, 15, 1883. The convention was called to order at 1 o'clock p. m. by President M. E. Mason.

After roll call and reports, the following officers were elected for the ensuing year: President, E. F. Mason, Jefferson, O.; Secretary, C. H. Coon, New Lyme, O.; Treasurer, N. T. Phelps, Kingsville, O.; Vice-Presidents, Ashtabula Co., O., D. H. Troop, L. D. Ormsby, C. L. Payne, P. F. Twitchel; Mercer Co., Pa., W. H. Fonner, J. P. Sterrett, A. Martin, S. Hogram; Erie Co., Pa., D. Videto, W. S. Stinson, D. W. Nichols; Crawford Co., Pa., D. Carkhuff, A. J. See, A. W. Anderson, Charles Olliver; Trumbull Co., O., J. S. Barb.

The first question presented for discussion, was: "The Best Method of Transferring Bees from Box Hives." Mr. Heddon's plan of drumming the bees out, was thought to be the best way, provided it is done when the weather is warm enough to prevent the brood from being chilled.

A member asked if it was necessary to keep the combs right side up when transferring them to the frames. Mr. Sterrett said he had put them in the frames bottom upwards, and found no difference.

"Best Method of Rearing Queens." Mr. Videto advised all to never try to rear them from dollar queens. He had tried it several times, and never got a decent one. He thought the best way was to get the best, to rear queens from. He always obtained better queens in a good honey season than in a poor one.

Mr. E. Mason said he would feed his queen-rearing colonies in a poor season, and thus rear just as good queens as in a good season. He thinks the position of the cells in the hive, quite important. He would place narrow strips of comb between the frames, near the top, and let the bees build the cells downward from them.

"Best Method of Introducing Queens." This brought out an animated discussion. Several gentlemen had their pet way of introducing, but it was thought the only safe way was to place the queen on a comb

of hatching brood. Mr. Ormsby said, he once tried, for several days, to get a colony to accept a queen without success. He finally removed all the frames from the hive, leaving the bees on the bottom board for a few hours. He then placed the caged queen in their midst, and left her till morning, when he liberated her, and in a few hours replaced the frames, and she was received all right. Adjourned to 7 p. m.

Evening Session.—Convention called to order at 7:20 p. m.

"What is the Best Way to Separate Two or More Swarms that Alight in One Cluster?" Mr. Videto has had as many as six swarms alight in one cluster. He has a long hive with division-boards, making as many parts as there are swarms in the cluster, and places a comb of brood in the centre of each part, with a frame of foundation, or comb, on each side of the brood; then empties the bees all together in front of this hive, and he usually finds a queen in each part next morning.

"The Best Method for Securing Comb Honey." Mr. Videto examines his bees as soon as he unpacks them, in spring, and takes frames of brood from the weakest colonies and adds them to the strong ones; thus, in a few days, he has half of his colonies very strong, and the other half very weak, and from these strong ones he always gets a large amount of comb honey early in the season. As soon as he gets them half ready for comb honey, he commences to build up the weak ones to run for the extractor, later in the season. Mr. E. Mason said, if we want plenty of good comb honey, we must have strong colonies early in the season. He would put on the boxes when the bees begin to build bits of comb on top of the brood frames. If the bees do not go up into the sections readily, take a frame of sections that are partly filled, and place it in the centre of the upper story, and they will usually go to work in them. Adjourned to 9 a. m.

Second Day.—Convention called to order at 9:15 a. m. President E. F. Mason in the chair. Several members addressed the convention on different topics, giving much information and advice, especially to beginners.

"Comparative Value of the Different Races of Bees." Italians were thought to be the best, all things considered. President Mason thought his blacks filled the sections fuller, and capped the honey better than the Italians, but obtained less honey.

"Best Method of Wintering." Mr. E. Mason thinks they should be well packed early in the fall, so as to get their house in order, before cold weather comes on; see that there is plenty of good, sealed honey, or, if the honey is not of the best quality, remove it entirely and feed them sugar. He has a few that are on the summer stands without packing, and they have come out several times, when it was too cold, and the ground around these hives are covered with dead bees, while those packed are in good condition, and he thinks they will stand it another month without a

flight. P. F. Twitchel, one year, packed all his colonies but six. Those packed wintered well, while the six, not packed, all died. Mr. Videto spoke of a neighbor who had a swarm alight on top of a fence, and he put a nail keg over them, bottom up, and they went to work in it and remained there all winter, with the bottom all open, and no upward ventilation; they came out in the spring, bright and strong.

My Report and Other Items.

R. GAMMON.

I have just been reading about large reports, separators, etc. I have no use for separators in getting my honey in marketable shape, and as far as half-pound sections, I shall not use any, at present; doubtless, there will be a sale for a few at good prices, but let the supply be large, and I doubt if they will bring any more than one-pound packages. I use $1\frac{1}{2}$ pound sections, and find no trouble in selling them at about 17 cents per pound. In regard to the large yields, I have not much to say, only I would like to know all the particulars in connection with it. I have never been able to obtain any such amounts, as

some say they have, but I have got nearly as good an average, per colony, as others, where the most of the honey was taken in the combs or sections; my average, last year, being 164 pounds per colony, spring count, and had but little increase. Last year my honey was all taken from clover and basswood, with the exception of about 200 pounds of fall honey; the average was 153 pounds from 16, in spring; increased to 23 by the nucleus plan; I made my increase late, so I took no surplus except from 3 colonies.

I am inclined to think there can be more honey obtained by letting them swarm once, if any one wants increase. The most I ever got from one colony was 238 pounds, part extracted and part comb; this colony did not swarm. Last year my honey was all white, and, of course, it was taken in much less time than the year before, when I got as much dark as light. This, I think, is owing to a better plan of getting my honey. It seems to me that one set of sections is not enough for a swarm of bees to work in, when you do not intend for them to swarm, as is the case with mine for the last two years.

Last year my best results were from my best Italians; this year it was from two queens which show the three bands only when filled with honey. I think there is a little black blood in them; still there are no bees wholly black; they are a little crosser than some of mine, but not bad. I have raised some queens from one, and will watch them with interest next summer. They may be something like Mr. Heddon's, but I see his average was rather small, as given at the Chicago convention. I have one of his queens, and expect to have some red clover honey to sell next year. The two colonies of dark bees gave 200 pounds each of comb honey, as near as I could judge by the sections. Rockton, Ill.

For the American Bee Journal.

Bee-Keeping in Missouri.

H. S. VAN ANGLE.

My apiary is situated on a high commanding table land, a short mile south of the Missouri river, in Lafayette County, Missouri, and its 90 odd hives of bees stand in the wintry air, on their summer stands, where they are kept throughout the year. This plateau is dotted over with an occasional oak, maple, wild cherry, and numerous apple, peach and apricot trees, flanked north and northwest by a back view of dwelling and out-buildings, and surrounded west, south and east by extensive fruit orchards, with a linden or basswood forest on the north. The hives are scattered and placed at unstudied, but convenient intervals over this lawn, tree-sheltered spot, singly or in rambling lines and irregular groups, under and among the spreading trees, most of them fronting the south, while, here and there, some face in other directions, but none west, and as they are mostly of the American type, and

painted white, it would not be a very lively stretch of the imagination to liken this bee yard, on some clear, placid moonlight night, to a ghostly cemetery, or during a genial summer day to indue it with the semblance of a picturesque, well-to-do and inviting hamlet of neat and cozy cottages, at least such are some of the conceptions and fancies that a few of the more visionary visitors entertain for it.

I am neither a specialist nor an expert in bee-culture, but manage, after an easy fashion of my own, to keep on hand, from year to year, about 100 colonies of bees—do not want any more—sometimes giving them a good share of attention, and then, again, in a great measure, neglecting them, having varying success according to season, attention given, etc. I have, up to the present winter, generally prepared my hives, in due time, for the cold months by the common method of quilts over frames, contracting the entrances, stuffing caps and all other available space with some good, porous material, and, sometimes, laboriously stuffing and sheltering, neglecting a few, by way of experiment, almost wholly, and have found the per cent. of loss to vary but little; and have but few dead bees.

The past season, however, my time was too much occupied with other things to fix up my hives as usual. On the last of November I removed the honey boxes and simply spread quilts over the tops of the frames, contracted the entrances, and left the hives in that condition throughout the weeks of terribly severe weather that ensued—the mercury in January scored 20° below zero, and lingered for days at a time, off and on, around zero and lower. An examination on Feb. 6, found all quite satisfactory, very few dead bees, hives full of life and vitality, and in first-rate condition. Then I had them well cared for, “tucked in” the neglected bees—something like taking in the grindstone after the cow had eaten it up. It is possible, however, that the severest test is yet to come with the varying climatic changes that will still necessarily occur. My experience in this latitude for a number of years past, with experimental hives and otherwise, is that bees simply but carefully fixed up for winter, have commonly come out in the spring fully as well or better than those so elaborately and circumspectly prepared after the “must be” plan of the would-be orthodox.

My best season's operation was when honey bore a better price than now. I received about \$1,200 cash for nice and fair comb honey sold from something less than 100 strong colonies, which were closely supervised and manipulated in a practical common-sense manner throughout the season. I rather incline to the opinion that a considerable part of the gratuitous advice, so freely offered, and promulgated as science in progressive bee-culture, is little better than “clap trap,” or in more familiar parlance, “humbuggery,” to accelerate the aims and ends of interested parties, but as I am not as full of ad-

vanced scientific and progressive ideas as some, perhaps I should be excused for my non-appreciation of the exuberant “pile on” in regard to the special make-up and material management of an apiary for profit that not unfrequently meets the eye in this excessive age of wonder and progress. An advanced idea that is given for what it is worth, is more or less acceptable and relished by the sincere and progressive, but an idea with a selfish handle, that is calculated to mislead and damage, should be indignantly repelled.

How to winter bees successfully is having much attention and study by able and comprehensive minds, and the various interesting experiments being made, notably those of chaff packing, may possibly go far towards a satisfactory conclusion, and, perhaps, after all that is said and done, some well devised and defined outdoor plan, wherever admissible, will be found superior to any special house or cellar arrangement. Such depositories are, to a certain extent, unnatural; the bees are put under a kind of surveillance, restrained and deprived of free action, and the possible sequence is debility and disease; whereas, the out-door methods allow them to indulge their natural instincts whenever a suitable opportunity offers, thereby enabling them to retain their normal condition, and are thus the better fitted for the active requirements of the hive with the opening of spring. I believe it is common for those who winter their bees in special repositories to complain more or less of “spring dwindling,” but this trouble I have almost invariably escaped, therefore, I shall continue to adhere to the summer-stand idea of wintering, as safest and best in all favorable localities.

Waverly, Mo., Feb. 15, 1883.

For the American Bee Journal.

Progressive Bee-Culture.

W. M. WOODWARD.

MR. EDITOR:—I want to congratulate you upon your success in giving us a really good BEE JOURNAL. So far as I know there are only about two other publications issued, even from progressive Chicago, that will compare with it. I wonder how many of us do not date a new era from the time the JOURNAL first made its advent on our tables.

I propose, with your permission, to say to the readers of the BEE JOURNAL: *Study the habits and instincts of the bees for yourselves, and make everything else conform thereto; hives, profits, management and all. Read for ideas, but “look before you leap,” for what will be a success with some one else by his methods, may, perhaps, prove a failure with you by yours. But, if you have the genius of a genuine bee-keeper, you will soon hit upon something that will be better suited to you than you will be likely to get by copying any one's fixtures.*

Conservatism has a proper place in bee culture, but its right use is in

holding on to the best, and only the best to be had, and not to a thing because our natural father's, or father's in bee culture, have used it. I say, therefore, if you can, make something good, use it and show it to your neighbors; but do not rush into the patent and monopoly business.

I hear a call for a "standard hive," which might be a good one, and it might be otherwise. It would, no doubt, be very convenient, but strikes the death blow to inventive genius, and makes bee-keeping a machinery business.

I am one of those who look for greater advancement in the future than in the past. A standard hive, fifty years ago!! Just think of it! A loggum manipulated by the brimstone match. We cannot afford to stop here; but let us rather "go on toward perfection." When I read the proposition for a vote on hives, I thought, why not change that a little and call for the *solid scientific principles* of a really good hive, and make all kinds conform to them, and thus get our standard hive. The number of hives is legion, but not so the good ones, much less the sound principles of hive construction.

I want to say to "Subscriber" of Milan, N. Y., that if he will take his American frames and put them in a hive, on Mr. Doolittle's plan, he will have no reason to regret it. I do not use the American frame, but would use it so, if at all. In my judgment the American frame would be much improved by cutting, say, a 3-16 slot out of each side of the frame nearly to each end, letting the comb attach in the centre of frame, and using no honey-board. No trouble will be experienced if the bee spaces are not large enough to allow them to start comb up through them.

Custer, Ill., Feb. 3, 1883.

For the American Bee Journal.

Upward Ventilation in Winter.

H. L. JEFFERY.

In the BEE JOURNAL for Jan. 24, page 52, Mr. G. M. Doolittle tells us about trying the Hill plan of shutting off all, or nearly all, of upward ventilation. I have, for 2 or 3 years, been watching to see if Mr. D. would not say something about hermetically sealing the top of the brood chamber, but not one word, or even a hint, at it. In 1876, I had a very small swarm given to me, late in the fall, with not more than comb enough to fill two Langstroth frames, if it had been transferred, but I left them in the box hive and fed them some syrup; then corked the hive tight; I put the hive in a large dry goods box, in a very sheltered situation, and, in 1877, it was one of my best colonies. The same fall I took two hives that held 13 American frames each, and put the bees in the centre on 5 combs each, set up a tight-fitting division-board each side, laid some sticks across the tops, then covered with a cloth and put 4 or 5 thicknesses of heavy manilla paper over the top, and packed the

sides full, letting the paper extend front and rear, laid another sheet over the top of the hive and pressed the cap down carefully; this completely sealed them up, and they had more brood than any other 4 colonies put together, on May 1.

I have, since then, continued to practice the sealing method, more or less, every season, with perfect success. I have written to and talked with a number of bee-keepers about it, but it did not accord with the ventilation theory.

Mr. A. F. Moon once wrote to me "that what I know is worth as much to me as what others know is worth to them, if they do not agree with me." Now, that Mr. D. has started to use a sealing method, I feel confident, as he infers, that by this method one of the steps to successful wintering may be gained.

Mr. D. also infers that we shall hear of fearful mortality, this winter, among the bees. Jan. 30 I examined about 40 box and frame hives, and I noticed that the dysentery is beginning to show itself in all the frame hives, where there was any amount of bee bread; those having sugar syrup were clear, clean and bright; and those wintered on candy of honey and sugar, were as bright, clean and active as in summer. As Jan. 30 was the first day for bees to fly to any extent, since the middle of November, they had been shut in for 10 weeks or more, but their flying showed which were wintering best, before examination.

From what I have seen, for the past six winters, I am sure that the Langstroth frame, properly prepared, is just as safe as any. I have tried the American, Gallup, both Quinbys, a frame the size of the Eclectic, and the Langstroth; the advantages of the latter for surplus, more than compensates for its disadvantage for wintering. With a hive having chaff, front and rear, with 3 inches of chaff under the bottom board, and room on the sides for chaff cushions, a good tight-fitting enamel cloth over the frames, with a passage $\frac{3}{8}$ to $\frac{5}{8}$ over the top bars, and then some chaff on top of the cloth, I will risk the best or poorest colony on the Langstroth frame as quickly as any other.

I have noticed, so far this winter, that the box hives are taking a cleaning out that will make them beautifully scarcer than they were one year ago, and those in frame hives, properly cared for, are laying. My bees are not suffering much this winter; about 19 per cent. of the bees in box hives are playing out, so far, from all that I hear of.

Woodbury, Ct., Feb. 2, 1883.

For the American Bee Journal.

Central Kansas Convention.

In pursuance to a call, the bee-keepers of Central Kansas held their first meeting at Manhattan, Kansas, on Saturday, March 10, 1883. During miscellaneous business, a resolution was adopted asking the authorities of the State Agricultural College to

teach apiculture in connection with entomology. The treasurer reports finances in good condition. The secretary gave encouraging reports from this section of country. The association listened to a paper by Mr. Robert Corbett, entitled, "Hints to Beginners," which was just what we needed. Association adjourned to meet on June 30, 1883. Seven members signed the Constitution. We hope to meet bee-keepers from all parts of the State at our next meeting, so as to put us on a firm footing.

THOS. BASSLER, Sec.
Box 436, Manhattan, Kansas.

For the American Bee Journal.

Can we afford Half-Pound Sections?

W. E. CLARK.

The half-pound section has been receiving considerable attention. Of all the articles I have seen on that subject, the one by G. M. Doolittle, in *Gleanings*, for February, is the best; in fact, he hits the nail on the head every time. It will be well for us to read it carefully and profit by the advice he gives. He discusses the subject in a straightforward and unbiased manner; does not gush over, as some do, but gives the facts in a plain, business-like way, and I would say that it will be well if apiarists heed the advice given. It has become a fact, well established, that the smaller the sections the less honey you get. The great bulk of apiarists keep bees for the profit, and that comes from the surplus honey we get. Now, if cutting down the sections would raise the price of honey, so that we would realize as much for it as in larger ones, adding the shrinkage in quantity, extra expense, and labor, it would do; but past experience has taught us that it cannot be done. Let the half-pound box become the standard, and you and I will get no more for our honey than we do now for that in one and two-pound boxes. Is this our past experience? We think so.

Mr. Doolittle tells us, by testimony unimpeachable, that it cannot be sold in half-pound sections, for less than 46c. per lb., to warrant us in using them. Do you think Mr. Doolittle's views are a little strong? He does not give his individual views only, but they are backed up by figures and past experience that challenges successful contradiction.

The editor of *Gleanings* talks about catering to the wants of the consumer. Now, candidly, is it not the supply dealer that wants the half-pound section? There is a certain class of men, and we have some of them who are producers, but, as Mr. Doolittle says, have a restless spirit, always trying to have something different from anyone else, and this class have tried almost all kinds of occupation and failed. The Buncombe reports published by some visionary bee-men have called them into our ranks.

The general opinion of producers is that we must get double the price for honey in half-pound sections that we do for that in the one and two-pound

boxes. We all know that when the half-pound box sells for 18 and 20c. per lb., as it certainly must, if it becomes the standard size, *that it will not pay*. Some say that we must use only a few half-pound sections. If the consumer wants them and is willing to pay 46c. per lb. for such honey, it is best to use them, and not until then. I do not believe that it is best to educate them to use them, but let them entirely alone. If producers wish to cut their own throats they will keep cutting down the size of sections, or will allow supply dealers to persuade them into using them. They will, perhaps, be wiser some day.

I have sold and produced honey for the last 25 years, and will say that cutting down the size of sections has never been called for by the consumer, but by supply dealers. This restless spirit, predominates I think, in the supply dealers. There is no general demand for a half-pound section. I have taken some pains to find if there was any call for them, and I never have found a buyer that said there was a call for it by the consumers. Mr. McCall, Thurber's agent, says there is no call for them in New York city.

The facts in the case are just these: one of two things must come to pass, if the half-pound box is used, honey-producing will become a non-paying business, or the consumer must pay double the price he now pays for comb honey.

Oriskany, N. Y., Feb. 20, 1883.

For the American Bee Journal.

West Texas Bee-Culture.

T. C. GREENWOOD.

Our winter is now nearly over, having been not the severest we have ever had, but a very cold one. Our bees have come through all right, and have been bringing in pollen for two weeks. We have no flowers yet visible, and where they get the pollen from we do not know; but surmise it is obtained from the little buddings of the long moss, which grows profusely in our river valleys.

I experimented somewhat in my wintering; placing some colonies in the lower Langstroth story, covering the cloth above with cotton seed; others I left with upper story on, giving them also a covering of seed. I can discover no difference in them now; all being right, with laying queens, now actively breeding up. This early active breeding is not desirable in this latitude, it promises early swarms; but where rapid increase is not desirable, it is troublesome, as our honey, from our main honey plant, does not reach us before the first of May.

I commenced, last year, with 24 colonies; increased to 49, and obtained over 2,400 lbs. extracted, and over 200 lbs. comb honey, in one-pound sections. From one colony, transferred from a box hive March 20, I obtained 195 lbs. extracted honey and one swarm of bees. From a colony swarming out on the same day, I ob-

tained 145 lbs. by tiering up to four stories. This last item explains to our Northern friends the wonderful reports coming from Texas, made by some of our enterprising bee-keepers. "Spring count," in this warm climate, does not remain spring count long, and a vigorous swarm emerging in March, by judicious management, can be made ready for work early in the honey flow, and increase the general average greatly. Northern brethren, who doubt our occasional enormous yields, may make a note of this, besides remembering that such a honey flow, as we had last year, is seldom seen in Texas.

I have resided in Texas 30 years; have had bees for 20 years; have run against several "patent hive" vendors, who "bled me some," and only last year "got down to work" in the Langstroth. In some seasons our honey flow is immense, sometimes from honey dew, mostly from flowers, especially the "mint;" but in other years, as in California, we get nothing. Western Texas is, on the average, a good honey country, and bee-keeping, on the right plan, will undoubtedly pay here. We are improving our colonies with the best Italians; have been patiently awaiting the results of Northern experiments with the Cyprians, Syrians, etc. Our three well-defined races here are enough, just now, for us. Our little black bee is irritable enough to teach us to avoid some of the others that have been tried. Our brown bee, mixed with the Italians, is a decided success, the cross producing a wonderful worker, not always irritable, and exhibiting the traits evidently best in both races.

The excessively prolific bee, so much desired by many up your way, is not the best for us. We have plenty of time to get ready for the honey flow; and too much swarming is decidedly troublesome, and sometimes attended with loss as well as inconvenience. I witnessed an amusing illustration of this, at the apiary of my friend and neighbor, J. S. Tadlock, last year. He is one of our most advanced and enterprising bee-keepers, had purchased one of Root's chaff hives, and had it already for work, last spring, in crack order. He gave me to understand, that with that colony, he was going "to trump" Mr. Eckman, a bee-keeper on the Brasos east of us, who had, the year before, obtained 450 lbs. from one colony, and bragged about it in the BEE JOURNAL.

Well, the chaff hive became full of bees. He declared there was one-half bushel of them, and so there must have been, for I called to see him, and looked at them myself, admiringly. They were in fine order, and the honey just flowing in, "so to speak." I went again next week; it was early in May, and immediately noticed that there were but few bees flying in and out of that chaff hive. Mr. Tadlock explained. Says he: "I went around the other day, suspecting nothing, when I discovered they had swarmed, in fact, nearly all went off, and we knew nothing about it. How they got away thus, I do not know." He

did not run that colony against Mr. Eckman last year, but he went quite up to his figures, with several others. He is an excellent man, enjoys a joke, and will pardon me, I know, for telling on him, how he intended to "lay it on" Mr. Eckman.

Our people here are not yet trained to eat honey a great deal. We sell our extracted at 10 cents and our comb honey at 15 cents. Bee-keeping, in fact, is not regarded as even business with most of our people, but we have some few men all over the State who are abreast of the times, and who are opening the eyes of the old box-hive men.

With the excellent BEE JOURNAL on my table (many single articles worth more to me than the subscription price), surrounded with the appliances of our fascinating art, I am well pleased with my progress. I notice one fact: wherever the JOURNAL is taken, the patent hive "mothtrap man" disappears, no more to return. To the JOURNAL and other similar publications, wherein Heddon, Doolittle, Dadant, Pond, Hutchinson and others give us their best thoughts, we owe a great debt of gratitude.

Luling, Texas, Feb. 20, 1883.

Convention Notices.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.
Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nelle's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.
Christiansburg, Ky.

The regular meeting of the Farmers' and Gardeners' Club, will be held April 2, at A. Z. Madison's office, Fredonia, N. Y. Question: "Bees, Fish and Poultry." Mr. U. E. Dodge will open the discussion with a lecture on "Bees and Bee-Culture," giving practical manipulations of the hive, showing the various improved implements, devices and terms used in bee-culture, illustrating the lecture with a colony of bees. Bee-keepers are especially invited to spend the afternoon at Sunshine Apiary, where Mr. Dodge will try and entertain them. Mr. Dodge is a thoroughly practical apiarist, and this will be a rare treat for bee-keepers in Western New York. Means will be taken to form a Bee-Keepers' Association for this part of the State.

A. Z. MADISON, Sec.
U. E. DODGE, Pres.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Saving Queenless Colonies.

My bees had a good flight on Feb. 28; they have been confined since Dec. 1. I examined all, and they were in good condition, covering from 5 to 8 frames, Langstroth size; they have consumed more honey and come out stronger than at any time for 5 years; 2 are queenless, and 7 have more or less brood, out of 10. 1. Can I get queens from the Southern States soon enough to save them? 2. How much candy, per week, will it take to carry a 7 Langstroth frame full of bees through? My bees are most as strong as they were last fall, and have no dysentery. D. S. BURBANK.

Grundy Centre, Iowa, March 1, 1883.

1. I think you can, but I cannot see that it will pay you, if you care for the queens *only* for that purpose.

2. I have never had satisfactory results from feeding candy of any kind. I feed liquid food, have just fed some few colonies, and one took down 6 lbs. in three hours. That colony is now off my shoulders for the season.

Spring Work.

I put 25 colonies into winter quarters, and all of them are doing well. I want to move them 2 or 3 rods in my yard. 1. When is the best time to do it? 2. How early in the spring shall I begin changing, reversing frames and feeding to stimulate brood-rearing? 3. How often should the frames be reversed? E. NEWCOMB.

Plank Road, N. Y.

1. At the first period, when they will be most likely to be shut in for a few days, by cool weather. When you move them, or just when they are about to fly from their new stands, smoke and jar the hives, and put boards before the entrances, so that they will bump noses, or have to fly out sidewise around it, and remove any fixtures from the old quarters that may make them "look like home."

2. After having fed and reversed frames, to stimulate early breeding for years, some years ago I abandoned it; and with hives properly made and arranged, no such practice pays.

3. As a rule, never; for the reasons before mentioned.

Bees in Texas.

I have kept bees for 35 years. Here in Texas, as a general thing, they do tolerably well. I have 90 colonies in frame hives. Last season was a fine season for honey. I took from 50 to 150 lbs. from each. I could have got $\frac{1}{2}$ more, if I attended to them, but as I have no one to assist me, and the

farm to run, the bees filled everything full of honey, and a great deal on the outside, before I could attend to them, and when I got to taking honey, I went at it with a rush, got the honey scattered around, and the bees went to robbing, and I have had a great deal of trouble. How can I check robbing? Some of my strongest colonies were diseased; the brood failed to hatch, and they became weak, and the moth and robbers destroyed about 20 colonies. The bees are all blacks; they seem to be wintering well, all on the summer stands. I never knew of any being housed here in winter. Our bees always go through the winter safe, when supplied with honey. The bees have had a flight every day for 6 days; the peach trees will be blooming in 2 weeks, if the weather remains favorable. J. E. JACKSON.

Richardson, Texas, Feb. 22, 1883.

First, in this branch of our business an ounce of prevention is worth ten pounds of cure. When once really crazed with robbing, the only practical way I know of is to remove the robbed colony to a cellar, give plenty of ventilation, and close up the hives. Protect the other colonies in the demoralized yard by close contraction of the entrances. If the weather is hot, shade or ventilate the hives at the top.

A Diseased Colony.

Last season my honey crop was about one-third. Bees gathered a good fall crop of fine quality. We had a very cold spell on Jan. 17 to 21; the thermometer was down to 18° above zero. On Jan. 28, my bees commenced carrying in pollen; we had one short cold snap since, and the bees are working now very fast on wild peach and dogwood; I notice one of my colonies has a strange disease; the bees crawl out of the hive in a trembling condition, turn over on their backs and die. Please tell me what is the cause of this? In regard to the use of separators, my experience is (and I believe that it is a good teacher), that with one-pound sections, filled with comb foundation, and with the use of tin separators, when honey is coming in fast, I can get as much honey as those who do not use any, and I know I can have nice, straight and well-filled sections. Everything bids fair for a fine honey season; peach and plum trees are in bloom, and farmers are planting corn. J. W. ECKMAN.

Richmond, Texas, March 5, 1883.

Having never witnessed any such phenomenon, I am entirely unable to account for it.

Destructive Birds.

Are martins destructive to bees?
Creston, Iowa. A. E. FOOTE.

I do not know, but I think not; at least, ours here are not known to eat bees.

Sundry Questions and Answers.

1. Is it necessary to have the tin bars and diagonal wires (as described in Mr. Root's circular) in wire frames? 2. Are queens, when sent by mail, wrapped up in the cage so as to be invisible? 3. Is an extractor, with its basket having slanting sides, an improvement over one having vertical sides? 4. How many Langstroth frames would you recommend for a hive? Will Mr. Heddon please give his reasons for using only 8 frames? 5. Would you recommend a hive with a permanent bottom and portico? A. S.

Newark, O., Feb. 24, 1883.

1. Not if you will put a proper amount of wood in the top bars of the frames, which I do, and prefer to the tin posts.

2. Not necessarily so; the law only requires that they shall be divided from the fingers of the mail agents, by double wire screens, with spaces between.

3. Not, in my judgment.

4. My reasons for preferring 8 to 10 Langstroth frames as the brood chamber of a colony, in brief (stripped of argumentative proof) are these: First, the capital rests in the combs, etc., and not the queen, since I want all that capital used to its utmost, and automatically so. Smaller brood chambers tend toward up-stair work in a potent degree. Narrower brood chambers (that is, fewer combs) are better for wintering.

5. After having used hives, in quantity, that had both permanent and loose bottom boards, and those with and without porticos, I prefer and use those without porticos, but always want my bottom boards permanent. Mr. Langstroth gave arguments in favor of tight bottoms, that, as yet, I have not seen satisfactorily controverted. My experience seconds his views.

Foul Brood, etc.

1. What is foul brood; does it, or can it proceed from chilled brood?

2. Would bees, that were healthy and clear of the disease in May, die of the disease by September following?

3. If you should take frames of brood from a colony in July to form a nucleus, and the old colony die in the fall, and the following fall you find that the nucleus has the foul brood, and no others in the apiary have it as far (as could be seen), would it not be very strong proof that it came from the frames forming the nucleus?

4. If there were no bees, either domestic or wild, within 4 or 5 miles, would there be any probability of bees, so situated, becoming affected from bees outside, and die in the same season?

5. Would you consider it square-dealing to sell a customer Langstroth improved hives and deliver the Simplicity, American, or any other instead?

6. Is it safe or prudent to try D. A. Jones' foul brood cure, before the middle of May, in this latitude, or until past freezing? Do you prefer it to any other way? I expect I have other colonies that may need to be treated for that disease in the spring, and you will confer a favor by answering these few questions through the BEE JOURNAL, with which I am so well pleased. O. B. SCOFIELD.

York, Maine, March 5, 1883.

1. I have never seen a case of foul brood. I suppose it to be a bacterious disease of the brood, and do not think it is caused by chilling at all. I know that chilling does not cause it alone.

2. "Bees" never die of or have the disease. It is a disease of the "brood;" it is not foul bees.

3. Yes; if the old colony had the disease, I should not expect such results.

5. Perhaps the Simplicity may be called, by some, an improved Langstroth, but I think it a degenerated Langstroth hive. However, I can see no reason for advertising the name as well as the kind of hive, where the name is so well established and known. Of course, it would not be right to send an American hive when a Langstroth was ordered.

6. I would rather wait till they fly, and draw out comb foundation for the new combs. I think that the plan of Mr. Jones is the best and most practical piece of advice ever given by him. The plan is in perfect keeping with the laws that I have always supposed governed all bacterial diseases, and not too complicated to be profitable to one who has many colonies affected.

Convention Notices.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address; Essays: Prof. A. J. Cook, on Wintering Bees; S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. WOOD, Sec.
North Lansing, Mich.

The Eastern Michigan Bee-Keepers' Society, will hold its annual meeting in Detroit, April 3, in Abstract Hall, commencing at 10 a. m. The following subjects will be brought up for discussion: What is the best means of extending the honey market? At what price can honey, either comb or extracted, be afforded? Is there danger of over-production? Has glucose affected your market, and if so, how? What is the best test for glucose? In judging queens, what points are to be considered, and what is the order of their importance? Foul brood, and its prevention and cure. An interesting meeting is expected.

A. B. WEED, Sec.

75 Bagge St., Detroit, Mich.

The Western Bee-Keepers' Association meets at Independence, Mo., April 28, 1883.

S. W. SALISBURY, Sec.

SELECTIONS FROM OUR LETTER BOX

A Bee Paradise.

What we lack here, to promote great interest in bees and honey, is simply first-class apiarists. Some of our best ones should come here and settle among us, in our most beautiful Shenandoah Valley, which is one of the best places on earth for raising bees and honey. Good crops of honey never fail here, though they are much better some years than others. We want good and true apiarists who will aid others in attending to their bees, rearing queens, furnishing supplies, etc. My apiary, "Bee Cottage," is about 200 yards from my main building, and it is surrounded by a pretty grove of evergreens. This is a great country for bees and honey, but there is not a single first-class apiarist in any of it. E. C. JORDAN.

Stephenson's Depot, Va.

[Here is a fine chance for those who want to escape the rigors of our Northern winters.—ED.]

Wintering Bees in Canada.

I had 3 colonies of bees in the spring: one Italian, and two blacks; increased to 9 good colonies, and got 98 lbs. of comb honey, and 12 lbs. of extracted. I have 3 on the summer stands and 6 in a neighbor's bee-house. I looked at them, and all appear in fine condition.

W. J. NORFOLK.

Stratford, Ont., March 12, 1883.

Bees in Splendid Condition.

Bees, in southeastern part of Indiana, have wintered well, so far as heard from. Mine are in splendid condition, although the weather was so changeable. I do not remember a winter as wet as the last. The mercury was 5° below zero to 60 in the shade. J. W. STURWOLD.

Haymond, Ind., March 9, 1883.

Bees Under the Snow Still.

My bees are all under the snow to-day, and it is still snowing. We have had 116 days of sleighing this winter, and prospects are good for it a month yet. March 1 and 2 were warm and pleasant days, and the bees had a good flight. My 80 colonies all answered to roll call; no signs of dysentery. J. H. KENNEDY.

Little York, N. Y., March 13, 1883.

Cheap Bee Feeder.

For a handy and simple feeder that costs scarcely nothing, go to the store where they sell cigars, and get the small-sized box, tear out the paper and take a piece of lath and saw it, so that it will fit across the short way of the box, $\frac{1}{2}$ inch from the end, and let it come within $\frac{1}{2}$ an inch of the top of the box and nail fast; then cut a hole in the small space at the bottom, and run sealing wax all around the corners and the bottom edge, and you will have a feeder not costing much, and as good as any. You can set it on the frames and feed at night, or you can put 4 of them on at once, if you want to. Put a stone or brick on the lid to keep the heat of the bees from warping the lid. For fall or spring feeding it is good and cheap, and any one can make it. March came in warm; the thermometer on the 1st was 61° above, and on the 2d it was 52°. I took a look through 4 colonies, and found them in fine condition, with brood in three frames. Bees have wintered well in this part of the country. R. P. WILLIAMS.

Goldsmith, Ind.

My Report.

Colonies in spring, 66; fall, 121; honey obtained, comb, 1,500 lbs.; extracted, 2,500 lbs.; total, 4,000 lbs. Wintering in bee-house, 106; out-doors, 15; loss in bee-house, none; out-doors, 5; on hand, 116 colonies. Frame used, Roop, 10x10.

C. F. HATHAWAY.

Chelsea, Mich., March 14, 1883.

No Flight Since Nov. 1.

My bees are in the cellar, where they have been since Nov. 1, and they have had no flight since. They are in excellent condition.

EMERY L. FRADENBURG.

Fentonville, Mich., March 15, 1883.

That Iowa State Convention.

I had 23 colonies last fall; packed 9 in chaff; put 4 in cellar; left the rest unprotected; lost one of the latter, and many bees have died in all the hives, reducing their strength sadly. I hope that some one will issue a call for that State convention at Des Moines. During the State Fair would be a good time. I think that M. Poppleton (being the vice-president of the National Association) is the proper person to call the convention. Iowa has many bee-keepers, but no conventions worthy of the name; no supply dealers, and is behind the times generally. Let us have a Convention. Dexter, Iowa. M. E. DARBY.

A Summer's Day.

After having three months of very cold and stormy weather, it was our luck, on the 1st day of March, to have one of the warmest of winter days. Had it not been for the snow in the fields and on the surrounding hillsides, it would have passed for a summer day. The bees enjoyed themselves on their wings from 10 o'clock in the forenoon till after 5 o'clock in the afternoon, and but very few were seen dead upon the snow, after they had had their frolic—it was a general turn-out. Who owns the largest number of colonies of bees in the United States, and how many colonies? Who owns the largest number in the world, and how many? What is the greatest number ever known to have been owned by a single individual? JONN MORRIS.

Mauston, Wis., March 3, 1883.

[These questions are much easier to ask than to answer correctly. We shall, therefore, not attempt it.—Ed.]

Notes from the Nauvoo Apiary.

I began the spring of 1882 with 90 colonies of bees, in average condition, having lost none during the previous winter. Had 6 colonies, pure Cyprians, with imported queens, the remainder mostly pure Italians, many of them with imported queens. The weather was very wet and cold up to July 4th, chilling large numbers of the bees, that left the hive for the fields, and the flowers giving very little, if any, honey, so that I was obliged to feed, up to June 20, to prevent starvation, and to stimulate them to raise brood. It was considerable expense, but I do not regret it, as it kept my colonies strong, and enabled me to reap a rich reward, later in the season. The white clover crop—3,000 lbs. of extracted and 150 lbs. of comb honey—was harvested the first 25 days of July, about one month later than usual. The fall crop began about one week after the spring crop closed, and ended Sept. 20, producing 11,000 lbs. extracted and 550 lbs. comb honey. This makes, for the crop of 1882, 14,000 lbs. of extracted and 700 lbs. of comb honey, together with 135 lbs. of beautiful wax obtained from the cappings. I had an increase of 24 colonies, three-fourths of them by natural swarming. My wife did all of the work of the apiary up to extracting time, when my vineyard and other labors were sufficiently advanced to allow me to turn my attention to the bees. My wife and I did a good share of the extracting, without any assistance. We often took off and extracted 2 barrels (1,100 lbs.) of honey per day, besides returning the empty boxes to the bees in the evening. My bees were put into winter quarters, on their summer stands, during the last days of November. They are packed according to Mr. Chas. Dadant's method, and have wintered very well, thus far. They had a good flight the first three days of last week, and I find that they are all alive and in comparatively good condition; even a very weak colony

that was queenless, last fall, for more than 6 weeks, and which I had not time to attend to until the middle of October, when I gave it a queen. My last swarm was hived Sept. 3, and gathered abundant stores for winter, besides producing about 30 lbs. of surplus honey. (Thanks to comb foundation. I may here remark that I would not do without foundation, even though it cost me \$1 per pound.) I have been in the bee business, now, 5 years, although I owned but one-half of the apiary until last spring, when I bought the entire stock. I have increased the number of colonies steadily every year, losing none, or next to none, in wintering. Have always wintered on the summer stands. My object is to produce as much honey as possible, therefore, I do my best to prevent swarming, and with good results, finding it cheaper to buy new colonies than to rear them. I expect to buy quite a lot this spring. Although I am engaged in teaching public school, and am obliged to be there every day, Saturdays and Sundays excepted, I have found but little trouble in disposing of nearly all of my large crop of honey, and at good prices, too. Have not dealt with commission men as yet. Our fruit prospects are "blasted" once more, as the vulgar saying is. Surely, this is a cold climate. I am seriously thinking of emigrating South. The only question is to find a suitable and agreeable location.

EMIL J. BAXTER.

Nauvoo, Ill., Feb. 26, 1883.

Wintering and Ventilation.

I see in "Bees in Winter" you mention seven things essential to successful wintering: may I add the eighth? A cleansing flight, once a month. Proof: One and three years ago, they wintered anywhere with that; while two and four years ago (and this), they died everywhere without it. An old bee-keeper said to me, "keep a bee dry and you cannot freeze it." How can we keep them dry, ventilate them properly (much has been written on that point), both at the top and bottom? I think G. M. Doolittle's article on page 52, present volume, is worth the cost of the BEE JOURNAL one year. It is right to the point: "just upward ventilation enough, and not too much." What would be just enough here, one year ago, would be ruinous this winter. That amount of upward ventilation, which is enough generally, would often carry off too much warmth; then the bees eat to keep warm; while, if a little more than just enough is given below, it would not do much harm, as I see. That article refers to A. G. Hill's success and experiments, and, so far, appears good, as per report. (Please report further; also W. Z. Hutchinson on clamp experiments, Geo. Grimm on cellars, and Heddon on out-door or chaff.) But, says one, snow blows in, when on blocks; true, make a hole in the bottom board or let the hive extend over the edge of the bottom board, a little. I often see accounts of bees in clamps, buried or covered in snow, where it is air-

tight above, and the bottom clear out (or large entrances), that bees came out in spring strong, lively, and in good order. Why? Because they are dry and warm. Page 69 shows that the air is about as pure near the bottom as at the top. To retain the heat, let out dampness and impure air, and let in pure air at the bottom—is not that better than to let both out at the top, and lose too much heat, and so have the bees eat too much? If much opened above, or they get damp by sweating, the bees soon die, also if too little opened at top. It is always hard to ventilate, upward, "just enough, and not too much."

Limerick, Ill.

E. PICKUP.

Zinc for Separators.

My bees have wintered well; to-day it was warm enough for the bees to fly, for the first time this winter. I put them out of the cellar, to give them a flight, and I had a chance to look them over. I found them in splendid condition except one colony, which was dead. I made a mistake in looking them over last fall; I did not notice that it had too much pollen in the hive. That was the only colony that had the dysentery; the rest are all strong and healthy, and I think will come through all right. It has been a hard winter on bees; it has been so very cold. Will zinc do for separators? We can get zinc cheaper than tin. H. J. SMITH.

Burlington, Wis., March 13, 1883.

[Zinc corrodes much more easily than tin, and is, therefore, not desirable.—Ed.]

Bees Wintered Well—Never Better.

My 130 colonies came through without loss, and in splendid condition. I have wintered, for 11 years, on an average, about 120 colonies in my bee house, and have only lost two colonies in the whole time, and they died of starvation. My bees never had dysentery, except in nuclei. Cold, bad honey, and the want of sufficient ventilation, are undoubtedly the chief causes of dysentery. The right temperature is about 45° to 50°. My average of honey for the 11 years has been about 80 lbs. per colony of extracted honey. E. C. L. LARCH.

Ashland, Mo., March 12, 1883.

Early Breeding, Etc.

My 40 colonies of bees are all on the summer stands, protected, as in former winters, in Armstrong's Centennial hives, and in spite of the severe cold weather ever since Nov. 27, 1882, till to-day; only 6 days in that time that bees could fly; 8 days in the time it was below zero; one day it was 12 below, and to-day it is 70° above, at noon. I have, to-day, examined my bees, and, strange to say, I found egg larva, young bees hatching, young brood hatched, and some of the hives are full of bees in every colony. Ten colonies have consumed nearly all their honey; so I put capped comb honey in place of empty frames, and I scraped all the dead bees and filth out, which I can very

easily do, as I can move the frames in the rear of my hives without taking them out of the hives, and almost without disturbing the bees. My bees are in splendid condition. S. E. Brown has 8 colonies; Robert Stevens has 10 colonies; M. Harneigan has 2 colonies, and John Snyder has 3 colonies, all on their summer stands in good condition, and all Italians but one. They are all in the Centennial hive, protected as mine are. On the 2d and 3d inst. we had the heaviest sleet I ever saw; it did great damage to the Judas trees, willow, peach, cherry, and plum trees. Some ask about the marks of the Holy Land bees? In reply, I say I have several pure colonies of them, and when the weather is warm, it never gets too dark, nor rains too hard for them to meet their visitors at the gate; if you just tap at their door steps, in a moment they will make you acquainted with their natural markings. I have 1 colony that can sting through buck gloves, and I do not see any difference in them and the Italians, in winter breeding. The deepest snow was 6 inches, and the prospects for 1883 are good yet.

R. M. OSBORN.

Kane, Ill., Feb. 14, 1883.

Some Corrections.

DEAR MR. EDITOR.—I think I am wrongly reported in the matter of "Overstocking," as given by the secretary of the Northeastern Michigan Association. I did not mean to say that it is well-nigh impossible to overstock a locality. In fact, I incline to the opinion that it is quite possible. I only said, or meant to say, that the matter was involved in doubt. That, perhaps, we had been all wrong in this matter. In notice of Central Michigan Association, I am represented as president. The Rev. Mr. Ashworth fills that office, and so well, that to him belongs all the honor.

A. J. COOK.

Lansing, Mich., March 9, 1883.

[We cheerfully make the corrections, but in both cases, we give it exactly as the copy was written. The fault was not ours, therefore.—Ed.]

Experience of a Beginner.

I bought 4 colonies of bees and some empty hives of a neighbor who was going away, and put them in my front yard under some apple trees, last spring; on June 7, one swarm came out, and I put it into one of the empty hives, which I had cleaned, and from that time they kept me scraping hives and hiving them, till I had 19 colonies; then in about a week out came another swarm, and having no hive, I put them into a cracker box; before they all got in, out came another, and went into the same box; before they were all in, out came the third, and they also went into the same box; the next forenoon another swarm came out and pitched right for that box, and all went in. Then I had 4 colonies in a cracker box; they killed all the queens but one, and filled the box with honey. I put a 10 lb. box on the top, and that they

filled. I had two early swarms that each gave a swarm and stored 60 lbs. of comb honey each. I had from the 4 colonies, spring count, 440 lbs. of comb honey, and increased my stock to 20 colonies. I sold the honey at from 18 to 25 cents per pound. I then sent for the BEE JOURNAL and Cook's Manual. I sold 2 colonies in the fall; united 3 weak colonies, and bought 14 more. I packed one in sawdust, and one in clover chaff on the summer stands; put the other 27 colonies in my cellar; they are all doing nicely, so far. Would a refrigerator be a good place to winter bees in, where it is perfectly dry, has a circulation of fresh air, and will not freeze? Has any one tried it? It strikes me that it would be just the thing. I intend to build one to keep eggs in, through the summer, and I could keep my bees in it through the winter.

W. S. SQUIRE.

Emerald Grove, Wis., March 5, 1883.

Honey Season in Sweden.

The past season here was only a moderate one; not much swarming, generally. I had quite a number of swarms, and consequently my honey crop was proportionately small, only 12 pounds per hive. For the past 2 years I have given my bees plenty of comb foundation, and will increase the use of it, by hundreds of pounds yearly; all other bee-keepers here also commenced to use it liberally; when well made, it is invaluable. The winter came in very early, in the middle of October, and since then they have had no flight; still they are all right, on the summer stands, packed in chaff, and well ventilated in front, half the way down—an essential thing in wintering successfully.

T. G. STALHAMMER.

Gothenburg, Sweden, Feb. 2, 1883.

Bees Carrying in Flour.

My bees have wintered well, and are strong and lively. They are carrying unbolted flour at a lively rate. They have brood in all stages, and young bees taking their first flight. They were wintered on the summer stands. I lost 2 weak colonies that were queenless until late in the fall, and let one good one starve to death. I have 41 colonies, all in good condition, and I have no fear of spring dwindling. Half of them are Syrians.

M. MAHN.

Huntington, Ind., March 9, 1883.

Bees in Canada.

As far as I can learn, what few bees are kept in this section of country, are doing well, in spite of the severity of the winter. Since they were packed for the winter, the mercury has only once or twice, for a few hours, stood at 40° in the shade, so there has been no chance for a flight, and to-day, Feb. 26, old Boreas is roaring away as if his strength is not nearly all expended yet. I have 9 colonies in a bee house, all doing well, as far as I can judge, though the temperature has not kept as high as I would wish, being from 31° to 38° most of the time.

Two colonies are out of doors in the Jones, wintering hive. In one of these the bees are so quiet I should suppose them to be dead, if I did not know to the contrary, and this colony has lost very few bees apparently. The other colony seems uneasy and noisy, and many more bees have died in the entrance and bottom of the hive than with the others. I wonder what causes the difference, as they are packed alike, and the entrances of both have been protected from drifting snow by small boxes set up in front. The first sunny day I shall try giving the uneasy ones a flight, by putting a large box over the entrance with a glass sash sloping like a hot-bed frame. I highly approve G. M. Doolittle's suggestions as to the way to use the BEE JOURNAL, and another time will tell you how I keep mine without the expense of binding.

HENRIETTA F. BULLER.

Campbellford, Ont., Feb. 26, 1883.

Fastening Comb Foundation.

The subject of inserting foundation comb has been very perplexing to many, though it seems so easy to me, and one of the least of the troubles with which I have to contend in bee-culture. The method I have adopted, I have used for 4 years, and is a success in every particular, and far superior to any I have seen or read of. For the benefit of the numerous readers of the BEE JOURNAL, I will try to give a brief description: I use a tunnel, about 3 inches in diameter, and, say, 4 or 5 inches long (that is the cylinder), with an abrupt tapering off to about $\frac{1}{2}$ inch, then a long, slim tapering (say 5 inches) to a point, only leaving a small hole, say, 3-16 of an inch. The top has a circular handle made of tin, with an opening, through which a wire, bent with openings to admit a finger, by which it is regulated, and said wire passing from the hand (top) entirely to the bottom, closing the hole, from which, when lifted, the melted wax, contained in the tunnel, flows, and is thus moved along the line where the comb is to be attached to the frame, thus welding it solid. The comb is, of course, joined, placed in the inverted frame, with a cross-bar, cornerwise, just to steady it, during the operation. I can set foundation comb of any width in 100 frames, perfectly, in less than 20 minutes "by the watch," and it will sooner break somewhere else than come loose from the frame.

Elroy, Wis.

D. C. TALBOT.

My Bees All Right.

My 21 colonies of bees came through the winter without the loss of one. They commenced brood-rearing on Feb. 7; brought in pollen on the 21st, and have been at it ever since, except a few days. We had a light frost on March 6, which stopped the bees a day or so. I was looking over some of my colonies to-day, and found hatching brood and some sealed drone comb. Fruit trees are in bloom, and bees are doing finely.

MARVIN M. BINKLEY.

Sherman, Texas, March 12, 1883.

Special Notices.

Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 A. M., March 19, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—It is quite scarce. I am paying 30c. for good yellow wax, 50 arrival; dark and off colors, 17@25c.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival.

BEESWAX—Comes in slowly and brings 20@30c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 10c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12@14c. to 14c. Extracted, 8c. to 10c., according to color.

BEESWAX—32@33c. per lb. for good. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—The market is dead and prices are nominal. No choice, no quantities are offering. White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9c.; dark and candied, 5@7@7c.

BEESWAX—We quote 30@33c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16c.—some inferior sold at 10c.; strained at 6@7c., extracted at 7@8c. etc., lots in small packages more.

BEESWAX—Scarce and wanted at 33@33c. W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is very slow, just now hardly anything selling, stock on hand quite liberal. Sales slow at 19@20c. for best white 1-lb. sections; 18@19c. for 2-lb. Second grades not inquired after. Extracted very dull at 10@10c. in bbls. and 11@13c. in cans.

BEESWAX—Scarce, 28@30c. A. C. KENNEL, 115 Ontario Street.

NEW YORK.

HONEY—The prospect is very poor for selling honey in this market. I think there is all the honey here that will sell this season, unless it sells faster during the next month than it has this.

BEESWAX—There is only a moderate supply of beeswax and prime lots held firmly.

Western pure, 30@32c.; southern, pure, 31@33c. D. W. QUINBY, 105 Park Place.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Dr. H. Besse has sent us a sample of his wooden separators. They are very nice.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

COMB FOUNDATION.

Owing to the scarcity of beeswax, the prices of comb foundation will hereafter be as follows:

	Dunham.	Thin.	Extra Thin.
10 lbs. or less.	55c.	52c.	50c.
25 " "	54	51	49
50 " "	53	50	48
100 " "	52	49	47

ALFRED H. NEWMAN,
923 W. Madison St., Chicago, Ill.

BEES FOR SALE!

Having wintered my bees safe, I will spare 10 or 12 Italian colonies, in Langstroth hives. New queens, but purity not guaranteed. 1 to 3 colonies, \$10 each; 4 to 6 colonies, \$9 each; 7 to 10 colonies, \$8.50 each; 12 colonies, \$10. In shipping boxes, \$1.50 less for each colony. Address—

R. M. ARGO,
Paint Lick, Ky.

WOOD SEPARATORS!

PRICE LIST of the Besse Wood Separators: For the wide Langstroth frame, per 100, 50c.; per 1000, \$4.00. They are of basswood, size 17x30x1-16. Any size to order. Send 3 cent stamp for sample.

12A31 DR. H. BESSE, Delaware, Ohio.

BEE KEEPERS' SUPPLIES!

Simplicity and Cheap Hives, Queens, etc. Send for Circular. Address,
HOWARD NICHOLAS,
12A41 4B1t Etters, York Co., Pa.

Wanted for Eastern buyers. Stamp for information. S. P. BLOCKWAY, Times Building, Chicago, Ill. 12A4t

100 COLONIES ITALIAN BEES, FOR SALE,

also, queens and nuclei. Will exchange for Jersey hives, pair Poland China pigs, or Plymouth Rock fowls. Write for prices.

C. WEEKS,
Clifton, Wayne Co., Tenn.

FOR SALE. Colonies and Nuclei of ITALIAN BEES, QUEENS, EXTRACTORS, BEE BOOKS, and Supplies. Address: OTTO KLEINOW, opposite Fort Wayne, DETROIT, Mich. 11AB3t

Vandervort Comb Fdn. Mills,

Send for Samples & Reduced Price-List. 10A1B1 J. VANDERVORT, Lacyville, Pa.

Colonies, Nuclei and Queens

FOR SALE CHEAP.
For terms, address
S. D. MCLEAN,
10D4B31t COLUMBIA, TENN.

(ESTABLISHED 1864.)

BEE-SUPPLIES.

We furnish EVERYTHING needed in the Apiary, of practical construction and at the lowest price. Satisfaction guaranteed.

Send your address on a postal card and we will send you, free, our large, illustrated catalogue.

E. KRETCHMER, Coburg, Iowa.
11A24B1t

1883. YOU GET VALUE RECEIVED! 1883.

QUEENS, BEES AND SUPPLIES

If you want **EARLY QUEENS** from the best improved **genuine** stock for business; or if you want Imported Italian Queens or bees, in full colonies or nuclei, with tested or untested queens; if you want Dunham or Vandervort comb foundation, made from **pure** beeswax; or if you want hives or apiarian supplies of any kind, send for my new catalogue. It tells you about introducing queens, new "Races of Bees," etc. Cash paid for clean beeswax. Address,

J. P. H. BROWN,
5BD15t Augusta, Georgia.

THE NEW IMPROVED STEAM POWER Comb Foundation Factory

CHAS. OLM, Proprietor,
FOND DU LAC, WISCONSIN.

Best work and pure beeswax is warranted. Send for Sample and Circular. 8D1t

CUT THIS OUT And Return to us, with TEN CENTS, and you will receive money in One Month than anything else in America. Absolute Certainty. M. Young, 173 Greenwich St., New York.

OLDEST BEE PAPER

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

"Rational Bee-Keeping."

On account of the crowded state of our columns during the past month, we have not been able to find room to notice or review the new book of the great German bee-master—the Rev. Dr. Dzierzon. We will now very briefly do so.

The work contains 350 pages, and is handsomely printed on good paper, with nice, clear type, and will be read with a great deal of pleasure. The author, in his preface, remarks as follows: "The theoretical part has been treated but very briefly, and with special regard to practical bee-culture—the author's aim being to show how to keep bees rationally and profitably, and at the same time to enable bee-keepers to satisfy themselves and others as to the reason for the different operations in their apiaries; *for he only is entitled to be called a rational bee-keeper who clearly comprehends why a thing is done in a certain way, and not in any other, and who is able and gives the reason for everything he does.*"

Concerning foul brood, the Doctor remarks as follows: "It is well known that, recently, salicylic acid has been recommended as a remedy for foul brood, the most dangerous of all the diseases of bees, and the method of treatment has been made known by Mr. Hilbert. Formerly, he advised spraying with diluted tincture of salicylic acid, but more recently he advises fumigating with refined powdered salicylic acid, strewed on a metal plate and heated over a flame. Since this treatment is much simpler than the repeated spraying of the

separate combs, and is applicable even to hives with immovable combs; the author thought it ought not to be left unmentioned."

The Doctor devotes 8 or 10 pages to a description of this dreadful disease, its symptoms and cure.

This great bee master strongly advises providing bees with pasturage by planting for honey, and speaks of the many uses to which honey can be devoted—making pure wines, metheglin, honey cakes and pure sweetmeats—instead of depending on adulterated and poisonous wines and sweets; and he adds most confidently: "There is no need, therefore, to be anxious about what is to be done with honey, even if the pursuit of bee-culture becomes more general and good bee seasons set in. At a moderate price, there will, even then, be no want of a market."

The book is the master-piece of a master mind, and should be in the library of every bee-keeper. The world has produced but few such intellects as that with which the Doctor is endowed. He is now the greatest living authority on bee-culture. To him, and the late Baron of Berlepsch, we are indebted for much that is now known in the realm of scientific and progressive apiculture.

We made his personal acquaintance in Germany in 1879, and though there were, at that Congress, the master spirits from nearly all the world, he was infinitely above all; and, to him, they all appeared to look for inspiration. He was, and still is, the great living Father of Bee-Culture.

The *Courant*, Berlin, Wis., remarks as follows: "Every bee-man should take a wide-awake bee-periodical, and the AMERICAN BEE JOURNAL of Chicago, is essentially that."

Articles for publication must be written on a separate piece of paper from items of business.

New Catalogues and Price Lists.

We have received the following new Catalogues and Price Lists of Bees, Queens or Apiarian Supplies:

B. F. Carroll, Dresden, Texas.
S. D. McLean, Columbia, Tenn.
Geo. W. Baker, Lewisville, Ind.
T. S. Hall, Kerby's Creek, Ala.
W. S. Pounder, Groesbeck, O.

SEED CATALOGUES.

J. W. Manning, Reading, Mass.—
Fruit Trees and Shrubs.
J. H. Walker, Worcester, Mass.—
Jersey Cattle.

Several bee-keepers of Eastern New York have written to us expressing their disgust at the resolution of the Albany Convention on the BEE JOURNAL. Among them, several of those present, including officers of the convention, who say that the matter was persistently forced on them, by the chairman, who, because some opposed the matter, left the chair in high dudgeon, and then was more highly incensed against the BEE JOURNAL than ever. The convention could hardly have acted more unwisely, or done itself more discredit, than to have been so foolish as to pass its insane resolutions.

The Lanark, Ill., *Gazette* pays this compliment to a well-known bee-keeper: "Mr. F. A. Snell, of Milledgeville, Ill., has the reputation of being one of the best bee-men in this section of the State."

Mrs. Lizzie Cotton's circular is again sent us, showing that she is still looking for investors in her bank, this time it is sent by Mr. Will, of Bloomington, Ill., who writes on the margin: "What do you think of this?" It is the old story; those who do not wish to lose their money, should heed the many warnings already published, from those who can get no returns (or some "worthless" hive) for their wealth sent to her.

CORRESPONDENCE

For the American Bee Journal.

What Shall I Feed My Bees?

ARTHUR TODD.

This question, as spring opens, will interest many bee-keepers. Some will simply seek to feed to keep alive those colonies that have not stored enough to last until plenty reigns. Others will feed to stimulate the mother bee to active egg-laying, and so, early in the season, have strong colonies. It is to the latter that these remarks are more particularly addressed. I purpose taking it for granted that those I address concede the principle of supplying their bees a spring feed of some sort, with a view to practising this cardinal virtue in bee-keeping, viz.: "Keep your colonies strong." I purpose to point out certain substances that may be employed, and the manner of so employing them, that remarkable results may be obtained by those who chose to give the matter of intensive feeding their careful attention, this spring.

This spring feeding is a sort of mild deception, played upon the mother bee, for feeding being once regularly entered upon, the bees get daily more active, and, literally, force food on the mother bee, making her believe that the time to be "up and doing" has arrived; a little earlier than usual, she may think, but still it has come. So, as long as the workers keep on assuring her that spring has arrived, she deposits the eggs which are to be the groundwork of the success of her colony.

Now comes in the question, "what shall I feed that shall induce those worker bees to overfeed the mother bee, and force from her a supply of eggs, equal, if not greater than it would be at the most favorable natural period of the year. As spring opens, we see carried into the hives, first, that substance called pollen, obtained from flowers. It is now known that bees eat pollen, and, moreover, feed it to the young, growing bees, hence its old name of "bee-bread." That pollen is eaten, the microscope proves, in the hands of a Scotch authority, who writes: "When I examined the excrements of bees, even when no brood was being raised, I found them largely consisting of the indigestible husks of the pollen grains."

Now, food is of various kinds, but all the constituents of food must be capable of assimilation by the animal eating thereof, and each constituent must go to repair a definite waste in the animal organism. In animal organisms we have three distinct classes of substances, viz.: mineral, non-nitrogenous, and nitrogenous. All foods may be classified as follows: Mineral—carbonaceous or respiratory (generally called heat givers); nitrogenous or nutritious (generally called flesh-formers).

All foods are principally composed of the chemical elements known as carbon, oxygen, hydrogen and nitrogen, combined in varying proportions. Under the head of mineral we class water, salts and ashes. A large proportion of all animals is water, and of this element of food a supply is required to replace loss by evaporation, and for the changes food undergoes in the body, while being dissolved, and made assimilable. What we know as salt, and the salts of various minerals, are of great service in facilitating the absorption of water, and building up the framework of the body.

The heat given from the non-nitrogenous portions of animals—starch, sugar and fat, are examples. These are highly carbonaceous, and, when taken into the animal system, there unite with the oxygen, and a slow combustion takes place, evolving what is known as "animal heat"; portions of these carbonaceous materials undergo various changes and are laid up in a solid form in the shape of fat in the animal body.

The flesh formers, or "nutritives," from the nitrogenous portions of animals—albumen, fibrine and caseine are examples. These all contain nitrogen, the element absolutely necessary to the growth and formation of organic tissues, by which all muscular force and nervous force is brought into action—bones, hair, skin, nerves, all require nitrogen to form them, hence the term "nitrogenous food."

Albumen is required by all egg-laying animals. Albumen is that form of nitrogenous food that goes to form nerve substance, and it is through and by the nerves, all animals are put in relation with the world exterior to themselves. By the nerves the senses are governed. Fibrine is found in the blood of all animals, and it constitutes the whole of their muscular tissue. Locomotion, whether by leg or wing, must spring from the presence of fibrine. Caseine is that substance which we separate from milk under the name of cheese, and is an essential of food. These elements of food are all to be found in the vegetable world, and it is plants that have the power of converting inanimate mineral substances into the necessary vital products of the whole organic kingdom.

At the opening of the year, bees have to provide for the animal heat necessary in the hive, the albumen necessary for eggs, and the growth of animal tissue in the young larvae and bees. Water (often impregnated with salts of the various minerals) is generally in abundance and easily obtained. To the vegetable world the bees go to obtain those heat givers and flesh formers I have mentioned.

Let us return to pollen and analyze it. Analyzed, it shows, in 100 parts:

Water	12.74
Ash	2.72
Albumenoids	21.75
Sugar	26.20
Nitrogenous organic substances	36.59

By this we see, pollen contains a portion of sugar essential to the production of animal heat, but the albumen and nitrogenous organic substances are *there* in large quantities.

Egg substance being composed of one-seventh pure albumen, contains, as already shown, "nitrogen," and the poor, mother bee, from whom we want to force some 3,000 eggs per day, must be fed nitrogen in ample quantity. From these eggs come the larvae and bees, all in a state of growth demanding supplies of flesh-forming and nerve-forming food. These albumenoids and nitrogenous, organic substances, shown to be, contained so largely in the first food the bee seeks in spring, *are*, as you can now readily understand, the most important to supply. "Nitrogenous food," therefore, is the answer to the question, "what shall I feed?"

The seeds of plants contain, in a varying degree, these flesh-forming or nitrogenous foods, and this is why artificial pollen, in the shape of pea, rye, barley, oat and wheat flour, has long been used in the open air as a spring stimulant, only, however, available on open, sunny days. Comparatively few have known the actual reasons why bees will take one kind of flour in preference to another. It is simply because there is, in some, a higher percentage of the nitrogenous element than in others. Rainy and windy springs, which prevented the bees from getting to the artificial pollen, gave stimulus to invention, and, at last, it came to be fed *inside* the hives, where brood-rearing could go on uninterruptedly, in all weathers.

The Germans long ago decided that there is an advantage to be gained by speculative, nitrogenous feeding of bees in the interior of the hive. In the spring of 1878, a German reports having obtained the most favorable results, and stated, that in his neighborhood, such was the miserable weather (cold winds, etc.) that not ten per cent. of swarms were reported, yet those who, including himself, fed the bees with flour inside the hives, increased their colonies 50 and 100 per cent. and had very good harvests of honey. Another renowned bee-keeper reported like good results. Scotch bee-keepers have long been stimulating in spring, by means of cakes, composed of rye flour, honey, etc. The composition of these cakes having been communicated to the Swiss Bee-Keepers' Society, that Society went to work in a very practical manner, got a baker to make the cakes, and ever since they have regularly advertised in the Swiss bee paper, "cakes of sugar, with or without flour."

In *Gleanings*, p. 249 (1882), we read: "A new substitute for pollen—cotton seed meal.—We have made a discovery which may be new: it is in furnishing bees material for pollen, they leave oatmeal, rye meal, and everything else for cotton seed meal, and they act as though they were perfectly happy with it, rolling and tumbling over each other in their eagerness. It may be the sweetness of the cotton seed meal that makes it so attractive to the little beauties. Please give us your opinion.—H. A. WILLIAMS & Co."

Again in *Gleanings*, page 302 (1882). "Cotton seed meal again.—My bees prefer cotton seed meal to any other substitute for pollen.—D. S. HALL."

Mr. Root remarks: "If I am correct, cotton seed meal has once before been mentioned, but if it is really a fact that bees take it better than oats or rye, it might be well to offer it for sale. Who will tell us what it is worth?"

I was sorry to see Mr. Root make no effort to fathom the reason why cotton seed meal is preferred to any other meal, his only idea seemed to be to find something to sell. The opportunity for teaching was there offered, and thrown away. Had Mr. Root investigated the point raised, he would have found that the proportion of nitrogen in cotton seed meal, to that in other meals, is as follows:

Cotton seed meal	contains	6.50	per cent. nitrogen.
Linseed cake meal	"	4.75	"
Bean meal	"	4.00	"
Pea meal	"	3.40	"
Oatmeal	"	2.00	"
Wheat meal	"	1.80	"
Indian meal	"	1.80	"

The wonderful instinct of the bee, therefore, guides it to select the food, that analysis shows contains the most "nitrogen," and, therefore, for open-air stimulation, when the weather is favorable, the substances, as in order named, will be found the best appreciated.

For intensive feeding, in the inside of the hive, there are many highly nitrogenized substances that may be employed to advantage. On some of these I experimented years ago, and I will now, having proved, I hope, the value of nitrogen as a bee food, mention some substances that may be employed, and methods of preparing the same.

Herr Weygandt (of Germany) prepared his bee food thus: "Take 1 pound of wheat flour, adding thereto either some salt or a little wine, then with water make this into a batter, by mixing carefully to avoid lumpiness. In another vessel put 2 pounds of sugar (or if honey, $1\frac{1}{2}$ lbs.), and mix this up in 1 or 2 quarts of water. This latter is now intimately blended with the batter, when it is ready for feeding." This food can be given thus or boiled. I gave it to my bees unboiled, and can testify to its ready acceptance by them.

My advice is to feed it by pouring over an empty comb, and hanging that, thus filled, in the hive. The bees suck up all the sweet liquor first, and a portion of flour remains in the cells, which they continue to dig away at, and, by degrees, carry it all off. It is best to do all feeding at night, then, if the morrow prove fine for flight, those bees, that can, will go out after the natural supplies.

Mr. Raitt (Scotland's most advanced bee-keeper) writes thus: "Three years ago a Highland lad told me his grandmother used to give her bees a barley bannock (or cake of barley meal), soaked in honey every spring, and that the bees ate all but the skin; this was the very idea I was waiting for. I had previously given meal in the open air; now I should try it in the hive. My bannock disappeared, and as soon as the bees began to eat it, brood appeared. Now, when I want breeding, I make easily dissolved candy cakes, with, perhaps, one-fifth of flour, or pea meal, in

them, and as certainly as I give them, they disappear, and brood appears. The bees cannot store away such pollen; they must utilize it somehow or other. They over-feed the queen, and she lays. They go on brood-raising in all weathers."

Of highly nitrogenized foods there are two, viz.: Eggs and milk, which I experimented with. In milk we have all classes of simple alimentary principles and substances together. It being composed of water, compound of chlorine salts (casein), fat and sugar, whilst the egg contains six of the alimentary principles, viz.: Carbon, hydrogen, oxygen, nitrogen, sulphur and phosphorous; all easily soluble and assimilable.

All concentrated foods are difficult of digestion, and so we supply a condiment to assist digestion, in the shape of common salt, either added to the prepared food, or dissolved in drinking troughs.

The milk food I prepare thus: The milk is first boiled as soon as possible after being milked, the clot removed, and then, if sugar be used to sweeten it, a pound of sugar is dissolved in each quart of milk. If honey be used, the milk must become cold before the honey (a pound to a quart) is added, and it must not be warmed again. Boiling prevents souring, and coagulates the excess of fatty matters which would be indigestible, and is best removed. In the milk of asses we find a poverty of fatty matters, and an abundance of sugar. Those who keep those interesting and intelligent animals will, I hope, take the hint, and feed their bees with their milk, and report results.

The egg-food I prepare thus: When a sufficient number of eggs have been broken into a basin, they are well whisked, and honey added in the proportion of double weight of honey to a given weight of egg substance. To eggs I have likewise added a sugar syrup made of 7 pounds of sugar to 4 pounds of water. This milk, or egg food, I used to give at night in tin or glass dishes, either inside of the hive or just at the door, the quantity being regulated by the size of the colony. The milk-food I gave every night, and did not observe any ill effects. The egg-food I used to give for two nights, and allow the third to pass without any. At each feeding, I gave what I considered adapted to the strength of the colony, increasing the quantity as it grew in numbers. Bees will store milk-food if allowed, so I took care to give only what they would consume.

I was interrupted, in a course of experiments I was about making as to the relative advantages of feeding the white of egg (which is pure albumen) only, or the entire egg. The entire egg contains a great deal of oily matter, sulphur and salts, the effect of which I had not time to note. Some colleague will, I hope, experiment further this spring.

In 1879, I wrote to a journal as follows: "The results are simply these, that by the above means you can start the queen laying at any moment, and as fast as the bees hatch out

strong enough to cover the brood, every cell of a fresh frame of empty comb you insert will be found to contain a freshly laid egg. I have one colony fed on milk-food only; six weeks ago it contained simply the queen and a handful of bees; they now cover four frames, having built out their comb from Raitt's foundation, and are busily engaged on a fifth. One noticeable fact is, that whereas those particular bees were weak and puny, never showing fight, the present generation are large, strongly developed bees."

From scientific investigation it would appear that the bees assist the mother bee's digestion by feeding her half digested, or chymified food, and thus convey into her system a larger amount of substances that go to form the eggs, than her unaided digestive organs could accomplish.

There are, however, two sides to every question, so I join my warning to that of the German bee-keepers, from whose writings I learned so much, quoting the words of Carl Zwilling, a noted Alsace bee-keeper: "Although there be apiaries at Lunenburg of 60 colonies, which, by speculative feeding increased, last year, to 300, it must not be forgotten that the men who did this are old hands at the work, that they know how to prepare not only the food, but the colonies to pass the winter, and the *when* exactly to apply the artificial food. All goes well if the bright, spring sun and mild weather favor the bees in their daily excursions, but if, with a bright sun, there should be sudden gusts of wind, or sudden rain storms, then the bees, tempted out of doors by the thought that the constant supply of nectar comes from the fields, instead of from man's hands, are caught, and chilled, never to reach that hive again, where the animal heat generated by each one is so much needed. A hive in this way may be quickly depopulated, and the brood be chilled."

Personally, I had ample proof of the wisdom of these remarks (and, if again feeding bees on nitrogenous diet, would place a wire gauze door to my hives, movable of course). Then, if windy weather sets in, with biting cold blasts, I would keep the door covered by the wire, shade all light off and keep the bees prisoners until the weather again became favorable; being careful, however, to see that the bees are not crowded for room, so that no danger from suffocation would arise, if they became excited on finding themselves prisoners.

I trust I have now, in some measure, answered the question, "What shall I feed my bees?" I assure you, I have but skimmed the surface of this most interesting subject. It is one well worthy of close and diligent study, and I hope some colleagues will experiment a little this spring, and, later on, give us the benefit of their experience. If I have, in any measure, suggested "food for thought," I shall be well pleased.

Philadelphia, Pa.

[The above was read before the Philadelphia Bee-Keepers' Association, at

a meeting held Feb. 12, 1883, when the following resolution was unanimously passed:

Resolved. That this Association recognizes, in the communication read this evening by Vice President Todd, entitled "What shall I feed my bees?" many points of great interest to bee-keepers generally, and hereby request the vice-president to furnish the Secretary with copies for publication.

He did so, and the secretary, Mr. F. Halman, Jr., has sent us the above, which, we think, a very valuable and scientific article, and one that will be read with much more than ordinary interest.—ED.]

Northern Ohio Convention.

The second annual meeting of the Northern Ohio Bee-Keepers' Association was held in Norwalk, O., Feb. 15, 1883: the meeting was called to order at 11 o'clock a. m., by President Samuel Fish, of Milan. Minutes of the last meeting were read and approved. The Society has over 40 members. The election of officers was postponed until the afternoon.

The first subject discussed was "The size of sections." Mr. Fish said, he was opposed to adopting any smaller sections than those now in use. While there might be a slight gain in price, in favor of the small section, such gain was more than balanced by the loss in the amount of honey stored. Mr. Hoyt was opposed to the use of small sections on account of the small difference in price between honey placed on the market in small and large sections. He said, however, that he was not yet satisfied in his own mind, which size was most profitable. W. H. Cole said, the larger the section the faster bees would store honey. He did not think that honey would sell for enough more in small sections to make up the difference in loss of the amount of honey gathered. He would not use the half-pound section under any circumstances whatever. Mr. Hurlbut said, that in his experience there had been no difference in the price of large and small sections. Mr. Gauff said, that his success had been, by far, the best with large sections. He thought that bees would store, at least, one-half more honey in two-pound sections than in one-pound. Mr. Sanders thought the use of small sections was like fencing a farm into small lots. It took too much time to do the fencing. It took the bees too much time to make the wax for the small sections. Mr. French had not had much experience. He had all his comb honey stored in sections, that would hold 5 or 6 pounds each, and sold it all at home, at a fair price. Mr. Darling said, the sections best adapted to the general market were the ones to adopt.

The majority of the members of the convention were in favor of using a medium-sized section, one that would hold about 1½ pounds.

Adjourned to 1:30 p. m., when the following were elected officers for the

ensuing year: President, Samuel Fish, Milan; Secretary, S. F. Newman, Norwalk; Treasurer, Joseph Gibbs, Norwalk.

After the election of officers, the president delivered the following address:

It is now one year since this Society was organized. Our meetings have all been pleasant and, I hope, instructive. It is pleasant to meet with old friends as well as to make new ones. As we know each other better, our ties of friendship will grow stronger and stronger. Bound together by our common interest in bees and honey, we may well greet each other with a smile and hearty congratulations. Anything that increases our knowledge of the honey bee and its ways and methods of working, or in any way increases the amount and quality of its productions, has real permanent value. An association which brings the bee-keepers of a community together and diffuses useful knowledge in respect to their calling, deserves our kindest attention and should be promoted.

The past season has not been one of the most profitable on account of the unpropitious weather; but we should not be disheartened. No, certainly not. We should have no disposition to give up. Does the failure of a crop of wheat, or corn, or potatoes cause the farmer to leave the farm? Such reverses seem only to stimulate the farmer to more energetic courage. Men to succeed in anything must focalize their energies, and learn that honest industry will be rewarded.

I wish to call the attention of this meeting especially to section honey. Bee-keepers who succeed the best are those who get the most honey from their bees. Most of us, I believe, use the Simplicity hive. The sections are placed in this hive in wide frames with separators. Is this the best plan? Are separators actually a necessity? Is there no way by which they can be abolished and still get honey in merchantable shape? If we can get 3 pounds of section honey without separators, while now we are getting but 2 pounds with them, we are certainly losing too much. If separators are necessary, would it not be better to discard tin ones and use something else? Some are having success with wooden ones. Bees certainly do not want so much cold metal near them, when they are making comb. Separators cost too much.

After-swarming is another trouble that bee-keepers are afflicted with, especially those who have bees enough already and want a good crop of honey. We all understand that, when bees once get the swarming fever, they abandon the surplus boxes, and we seldom get any more honey from them during that season. We have all felt this very keenly. At one of the conventions in the West, not long ago, the question was asked, "Can swarming be prevented?" and it was answered by Mrs. Harrison, a lady bee-keeper of Illinois. She said, "when you can prevent bees from swarming, you may, perhaps, also find out how to prevent the human family

from increasing. It cannot be done." As a rule it is best for a colony of bees to cast one swarm, and only one, but the trouble is to prevent it. I have controlled them somewhat by cutting out the queen-cells, but that is not a sure remedy. James Heddon says he does not believe in cutting out all the queen-cells but one, and then expect that one to give the future queen with the best results. A writer in the BEE JOURNAL claims he has accomplished this, and gives his method, as follows: "If this inordinate desire to swarm is manifest, there is still a way to satisfy the bees without lessening the working force in the hive. If the bees seem determined to swarm, usually there are several cases; if there is one, let the first swarm be placed in a new hive. When the second swarm—I refer to a swarm from some other hive—comes out, it will likely be on the same day; put this in the hive that swarmed first, after having destroyed all the queen-cells in the hive. This colony is just as strong now as it was before, in brood and bees, and the bees will be satisfied to settle down to work in the sections. A third swarm can be put in the hive from which came the second swarm; a fourth into the third, etc.

It has been supposed that the carbonic acid produced by the bees in breathing, on account of its being heavier than air, settles to the bottom of the cellar or bee-house. We have been told that it is necessary to raise our hives 10 inches from the floor to keep them from this poisonous gas, and sub-earth ventilation has been largely recommended to run this gas out of the way. The experiments of the scientific board appointed by the United States as a special committee on the ventilation of the Capitol at Washington, after a careful analysis, prove that this gas was quite evenly distributed throughout the building. If there was an excess in any given place, it was near the ceiling. This board of scientific men report it as a gross error to suppose that this gas falls to the floor, for, although when pure it is much heavier than air of the same temperature, yet air expired from the lungs is of higher temperature than the surrounding air at ordinary temperature, and the law of the diffusion of gases prevents any separation. This may seem strange and wonderful, but it is no more so than to have the amount of water in the atmosphere in a clear day, determined for us. Fortunately for bee-keepers, this board of scientists have solved the difficulty in finding the direction taken by the carbonic acid evolved by respiration. The detection of this gas and the amount the air contains requires skill, careful attention, and instruments of much perfection. Among them is one of recent date, the spectroscope. Powerful spectroscopes, in their early days, were used almost exclusively to detect, while in solution, the different kinds of metals and minerals. Quite recently this instrument has been simplified and reduced in size so as to be carried in the vest-pocket; but it is so powerful and true that it will determine for

us whether there is moisture enough in the atmosphere to produce rain within the next 24 or 48 hours. We can all see, at a glance, what benefits this little instrument will be to all classes of society, especially to the farmer who wishes to secure his hay and grain in the best condition possible. Bee-keeping of the nineteenth century is not adapted to the sluggard. That day is past. Let us all investigate, in the light of science and experience, as long as we can save one more colony of bees or cause it to produce one more pound of honey.

A vote of thanks was given the president for his able and instructive address; after which the address was discussed by nearly all the members present.

The secretary said, that the only sure method of preventing second swarms was the introduction of a queen immediately after the first swarm had left the hive. Every bee-keeper should have on hand, during the swarming season, extra queens for this purpose. Not only would the successful introduction of a queen prevent second swarms from issuing, but would largely increase the amount of surplus honey. The newly introduced queen would occupy the cells in the brood chamber from which young bees were constantly hatching, with eggs, thereby preventing the bees from storing honey in those cells, and compelling them to store it in surplus boxes above. If the colony from which a swarm has issued is left to raise a queen for itself, it will generally be queenless about three weeks, and consequently would contain about 40,000 less bees during the rest of the season than it would have contained if given a good queen as soon as the swarm issued; for the good queen will lay not less than 2,000 eggs every day during the honey season. Mr. Hoyt said, that he would have young queens to give colonies that had swarmed, if for no other purpose than to prevent the loss in bees that would occur by not having them. Mr. Fish thought that the secretary's plan of introducing queens would not prevent second swarms. It had not, in his experience. The secretary *knew* that it would prevent abnormal swarms. If the second swarm was normal, there was no loss resulting from it.

Mr. Beebe asked how to keep bees in the hives when they were wintered in-doors? Mr. Fish: Bees will not leave their hives if the cellar or beehouse is kept perfectly dark, and at the right temperature. Mr. Mackey said, bees should not be wintered in-doors except in a frost-proof receptacle. Mr. Hoyt: Bees should never be confined to their hives. If they were, for any length of time, they would become uneasy and would collect about the entrance in such numbers as to smother the whole colony.

Mr. Parkhurst asked if anything except bad honey produced dysentery in bees? The Secretary: Long confinement without flying, dampness, cold and hunger sometimes caused bees to have dysentery.

Mr. Hoyt asked how much chaff should be placed in the second story of hives in wintering bees? Mr. Cole: The more chaff the better for the bees. His colonies, which had the most chaff in the cushions above them, were in the best condition. Mr. Fish: When too much chaff is used it is likely to become damp and moldy, and thus cause the colony to become unhealthy. A thickness of 4 inches is sufficient. The Secretary: Chaff cushions should not be less than 10 to 12 inches in thickness. If they were only 4 inches thick they would not retain sufficient heat to keep the colony in a healthy condition. Thick cushions allow the moisture to pass off as readily as thin ones. While it is true that the upper side of a cushion is frequently quite wet, the lower side, which is next to the bees, is always warm and dry. The moisture on the upper side is produced by the warm air from the bees passing through the cushion and coming in contact with the cold air above it. Mr. Cole: Mr. Fish was mistaken; a constant current of warm air was slowly passing through the cushion and driving out the moisture contained in it, thus preventing it from becoming wet. Mr. Darling: Did not know anything about chaff cushions, but was successful in wintering. His hives did not have upward ventilation.

After a vote of thanks to the City Council of Norfolk for the use of the Council Chamber the convention adjourned to meet sometime during the month of April, 1883; day to be fixed by the secretary.

S. F. NEWMAN, Sec.

For the American Bee Journal.

Wintering, Ventilation & Dysentery.

DR. G. L. TINKER.

It has been stated that every plan of wintering fails at times, that what may succeed in one locality, or one year, may fail in another locality, or the next year. All of which, were it true, would be very unpleasant to the investigator, and discouraging to the bee-keeper. But, happily, every effect must have an adequate cause, and if one plan of wintering succeeds in one case, and apparently not in another, it is because the conditions have not been exactly the same. Of one thing we may be certain, that nature does not change her moods, and that, when we shall understand the right way to winter bees, it will be found neither complex, difficult to execute, or uncertain of result.

The great object to be sought in wintering has been well stated by Mr. Doolittle. It is, that we should know, and be able to place our bees in "the most favorable conditions." Beyond this we may not go, but to secure these conditions is to meet with undoubted success in wintering.

The writer has stated that "cold and dampness are the primary causes of dysentery." Now, the causes of this disorder may exist in varying degrees in different cases. We may have dysentery result in one case,

spring dwindling in another, or simply, imperfect wintering in others. The affected bees may survive the winter and spring, but not in that vigorous condition which is the evidence of perfect wintering. Thousands of colonies go into winter quarters in fine order every year and survive in this way, the outcome of "unfavorable conditions," and become of little profit to those who own them.

If bees become restless in their hives, and are seen to fly or run out in unsuitable weather, if they become torpid or exhibit signs of abdominal distension, or if, when they do have a good flight, after a month or two of confinement, they spot their hives badly, they have not had favorable conditions, and cannot, therefore, winter perfectly. It is considered a very great mistake to suppose that the bees that are sometimes to be seen coming out of their hives in winter, become chilled and die, are, as has been often stated, only old bees that were about to die. According to my observation, bees seldom fly out when it is too cold, if all is right within the hive, and the old bees are just as good as any, until they begin to take active exercise on the wing.

A colony of bees, wintering in good order, does not become restless, or fly out at improper times. Neither have they occasion to fly out for long periods, since they void their feces in the hive in the form of the so-called "dry powder," which falls to the bottom of the hive. Upon taking a flight they spot their hives only slightly, if at all, and are never seen in a distended condition.

To secure these desirable results it is only necessary that a colony be placed in such condition that it may easily maintain a temperature in any part of the hive outside of the cluster, of not less than 40° Fahr., in the coldest weather, while the temperature of the cluster itself should remain steadily at about 93°, which, from many tests that I have made at low general temperatures, seems to be the normal point in winter. The temperature, just above the bees, in the chaff, should average about 50° or a little above. If from any cause the temperature within the hive should fall much below these points, we shall then get unfavorable conditions, and the effects of dampness at once makes itself apparent.

There is a degree of temperature within a properly ventilated and protected hive of bees, outside of the cluster, at which the dampness arising will be forced outward, and beyond the reach of harm. This degree may be as low as 40°, but it is thought to be nearer 50°, from a table that I have prepared of tests conducted on six hives at once during the first eight days of February. It is believed that at 50° and above, the heat of the cluster, under proper conditions, is ample to force all dampness out of the hive. At this degree of temperature, the chaff above the cluster will always be found dry, except a portion on top, which may often be found quite wet or even moldy. This is to be removed once or twice during the

winter and replaced by dry chaff. I also believe that the state of the chaff over the cluster is, at all times, a reliable index of the state of the colony. If, on passing the hand down next to the frames the chaff is found to be sensibly warm, the temperature will range 50° or above, when we may know that all is right.

As the temperature in a hive outside of the cluster recedes towards the freezing point, the hive becomes damp, until moisture accumulates on the outside combs and the hive. From this excessive dampness and a rapid fall of the temperature of the cluster, the bees are forced to exercise their wings and to consume more largely of their stores, to keep within the limits of life. The air of the hive, being both cold and damp, rapidly takes the heat of the cluster, on the well-known principle that any warm-blooded animal more readily parts with its heat in a damp atmosphere, at a given low temperature, than in a dry one at the same temperature. Add, now, to this state of things the great difficulty in the exhalation of vapor from the air tubes, or respiratory apparatus of the bees, which has been so admirably demonstrated by Mr. S. Corneil (see page 728 of the BEE JOURNAL for 1882), and we have the primary causes of dysentery developed in full force. The normal exhalation of a vapor being arrested by a low temperature in a damp atmosphere, we have necessarily an accumulation of liquid in the intestines of the bees, and, being endowed with an instinct not to pass the unnatural excrement in the hive, they become distended often to bursting, and many may be compelled to void within the hive. Soon the entire colony becomes more or less wet, filthy, weak and cold, until all become extinct.

Now, if there is anything else to bee dysentery, it is of secondary origin. Changing states of the honey, as by acetic fermentation, from the development of some one of the many forms of bacteria, might thus act, and unsealed honey, as well as sealed, may absorb dampness until quite liquid, if the hive becomes cold within, and thus add immediately to the difficulty of exhalation.

Last of all, it might be supposed that the consuming of pollen could have something to do with it, but I have been unable to see how it could.

Pollen, being a nitrogenous food, is chiefly of service in the repair of the tissues of the bee, and is little consumed or required by a colony in a state of rest. If, however, a colony, owing to severe and protracted cold, or insufficient protection, or both, is forced to exercise to keep up the temperature, they would probably consume more pollen than at other times. But, even in such case, it would be very difficult to show what relation, if any, it might have to the disorder. It will be safe to remember the pollen theory as one of the curious explanations of the supposed cause of dysentery.

But, with proper ventilation and protection, the secondary causes may

be reduced to a minimum, if not entirely overcome. In at least one case of a late swarm, which was fed upon unsealed honey, in partly-filled sections, until there were nine frames nearly full of unsealed honey as late as Nov. 10, the colony has so far wintered in prime order.

The great mistake that has been made in wintering, is in giving too much upward ventilation. The practice has been to permit the escape of the heat of the cluster, in the effort to get rid of the dampness, by providing too many or too large openings in the cover. In permitting the loss of heat we have unwittingly failed of our design, since the heat is essential to force out the dampness. In fact, we have got up a condition to bring about the very thing we had sought to get rid of.

Proper ventilation of bees, in chaff hives, may be had as follows: Across the brood frames, place 6 or 7 pieces of wood, $\frac{3}{8}$ inch square, and apart about 1 inch. A single thickness of new cotton cloth is laid over them and the frames. The cap, which should contain about 1,000 cubic inches, is then filled with loose chaff (timothy hay chaff preferred), and gently pressed down until 7 inches deep. All holes for ventilation in the cover, which should fit tight as possible to the hive, are to be stopped with pieces of muslin or other cloth. The entrance should be $\frac{3}{4}$ inch by 8 inches, or an equivalent space. To prevent high winds from driving into the entrance, leave a board, 8 inches wide, up against the front of the hive. In very cold sections of the country, the bees should be crowded upon 5 or 6 combs, by a division board. Several of my colonies, prepared as above, did not get a flight for nearly three months.

After so long a confinement, I was surprised that some of them did not spot their hives at all, while the others dropped only tiny specks, which were quite unlike the spotting of those colonies having exclusive lower ventilation.

In a letter just at hand, Mr. Doolittle confirms the results of my experiments as follows: "I believe you are quite right regarding lower ventilation, in connection with chaff and a tight cover, for I have some colonies in that condition, and they are the best of any."

A colony of bees, in a chaff hive, on 9 Gallup frames, with strips of wood between each, and all sealed up perfectly tight on top, have wintered in fair condition with an entrance only $\frac{1}{2}$ inch by $2\frac{1}{2}$ inches, but the bees seemed too warm and are flying out, which, if they did much too often, would spot the hive badly. So also, another colony with a larger entrance, $1\frac{1}{2}$ inch by 13 inches. From this it would appear that dampness interferes with exhalation, even in a very warm hive, where the bees are unable to ventilate it. But if a slight amount of air can pass upward, through chaff, the benefits of both upward and lower ventilation can be easily secured.

New Philadelphia, O., March 7, 1883.

How to Use Bee Papers.

R. J. KENDALL.

The article by Mr. G. M. Doolittle, entitled: "The use I make of the bee papers," in your issue of Feb. 14, I read with a great deal of interest, as I do all his articles. I set considerable store by his articles, and to index them in a memorandum book which I keep for the purpose of noting these subjects, and to speak of it, is one of the objects of this letter.

The article alluded to, suggested to my mind that I might add a word on this subject, supplementing Mr. Doolittle's remarks. When the BEE JOURNAL comes, I get a blue pencil and sit down to read it, marking it as I go along; sometimes pretty fully, sometimes sparingly. When I have finished reading it, or a few days after, I go over it again, and index, under comprehensive or particular headings, some of the articles and paragraphs in it. I had not hit upon Mr. Doolittle's plan of indexing for times and seasons, but I shall at once take his hint and do so, for I see a valuable advantage in it, and excellent addition to my own plan. Mr. Doolittle's article gave me considerable comfort, too. I seem to forget so much that I do read, when compared with the little I remember. Dr. Johnson once said that "knowledge is of two kinds, the knowledge we have in our heads, and the knowledge we have on our shelves and know where to look for; and of the two kinds, when quantity and quality is considered, I do not know but what the shelf knowledge is the best." I have often thought of the doctor's remark, and I confess, have tried to utilize it, with advantage, and it was just this that led me to indexing my bee papers. I want an index before the one at the volume's end comes.

I believe much in theory, and Mr. Doolittle's remark that while he had gained considerable knowledge from conventions and visiting other bee masters, yet he obtained more from bee papers, fit me exactly. I can read the BEE JOURNAL for 10 or 15 minutes after my dinner, when I cannot visit an apiary, and can get out of it good matter, if it is there; and this leads me to make this remark, that any man who cannot make his business pay, had better quit the business on his own account and go to work for wages; the odds are against his success. An apiculturist who does not take a bee journal is to me a problem.

There is, however, one more thing I want to say and suggest, and it is this: Why do not local bee men form minor or sub-associations or clubs, never mind how few, and even if the clubs are (like Artemas Ward's regiment, which was all generals) all officers, they may still do themselves, I think, much good. Suppose there are one, two or four only in a district; if these met for a chat and "experience meeting," once in every two weeks, I think it would pay. They could unite on a plan of supplying

the local market or shipping to distant markets. These local clubs again could be units of district associations, and altogether a common plan of shipping or marketing honey could be adopted, that would enable them to unite, and, by their unity, work for the common good. They could resolve, for instance, on supplying such and such quantities of comb or extracted honey; they could educate the home market to either.

Suppose, for instance, the local market would take nothing but comb honey, and the bee-keepers in that locality wanted to introduce extracted. They could keep comb entirely out of the market, but supply and talk extracted, till the dealers and their customers, finding they had only Hobson's choice, "that or none," would try the extracted.

I live at Austin, Texas, and if there are any bee-keepers near, who agree with my idea, I shall be glad to hear from them.

Austin, Texas.

Bee Notes from Mississippi.

OSCAR F. BLEDSOE.

We have had an unusually severe winter on bees. Last season my bees gathered pollen in January. This season they have gathered it only at times during February. With Italians, swarming usually commences here during the last week in March. I do not expect any swarms now before the middle of April. I lost a number of nuclei and small colonies from starvation and robbery, owing to want of care, caused by my protracted absence during the fall and winter.

The conclusions I have reached about wintering bees in this latitude, is that with plenty of honey and a well covered hive, even very small nuclei can be wintered safely, out of doors—that the full amount of stores needed must be provided in the fall,—or the robbery of weak colonies will always attend, by any method of feeding in the spring, and that strong colonies, in large hives, winter best, even comparatively.

I have observed, with great satisfaction, that all the colonies in my large hive are in the highest degree of vigor. It has a short Langstroth frame, is 33 inches long, from right to left, containing nearly 4,000 cubic inches in the lower story, with a half story added, 4½ inches high, to contain sections. As a rule, I put on 35 sections at one time, immediately above the brood nest, leaving 4 frames on each side of the sections at the ends of the hive, easily accessible for manipulation at all times. I place the sections across the frames and prevent them from being glued to frames by a tin device of my own invention.

I use wooden separators, purchased in Memphis, being the material cut out of poplar, used for making strawberry boxes. They are much better and cheaper than tin. I chisel small

holes in them, so that, with the tin device, there is perfect intercommunication between sections and brood nest, and of the sections with each other. I think it very desirable not to be compelled to use brood frames. On raising the cover I can see what sections are completed, and take such out, one at a time, without disturbing the rest, and put others in their places. I leave the sections on, all winter. If I can make each of my large hives yield an average of 100 pounds of comb honey up to Aug. 1 (a point I am trying to attain), I will consider that I can make bee-culture a profitable branch of agriculture.

Grenada, Miss.

The Ventilation of Cellars.

ALLEN PRINGLE.

In a late BEE JOURNAL, Mr. J. B. Mason, of Maine, asks for information on the above subject. He wants a "rousing article on how to ventilate a damp cellar," with "plain, simple instructions how to do it." Now, if my article proves to be a "rousing" one in the sense of arousing people to the imperative necessity of thorough cellar ventilation for the preservation of their own health as well as that of their bees, I will feel repaid for the little precious time spent in writing this.

The amount of sickness, doctors' bills, and even death resulting from the foul air and poisonous gases of cellars without ventilation, would be quite appalling, were it adequately realized. The disease engendering blood-poisoning gases arise into the pantry and kitchen, and spread themselves through the whole house, to be taken into the lungs and blood of the occupants thereof, producing impaired health, sickness, and in many cases death, which, instead of being ascribed to a "Mysterious Providence!" Such, still, is life in this latter half of the nineteenth century. Intelligent people, who are fairly educated, and well posted in the ordinary sense of the word in all that pertains to business, etc., are lamentably ignorant of the very elements of physiology and hygiene. Of the laws and conditions upon which health and physical well-being depend, they know but little. Now, when we consider that such knowledge is really the most important of all knowledge, this is certainly a very bad state of things. And for its existence our educational institutions are primarily to blame. Self-knowledge should stand first on the curriculums of our schools and colleges instead of, as now, last, or not at all. Every parent should be competent to instruct his or her child in the elements of physiology and hygiene—in the laws and conditions governing life and health.

But now, as to the best methods of cellar ventilation. There are various plans, but the very best I have been able to find, and which is at the same time inexpensive and practicable, is as follows: There is, at least, one stove in every house, and sometimes two or three, standing over the cellar. We will begin with the cooking stove, which, in winter, is kept burning most of the time, night and day. Get a tin or zinc pipe, made from previous measurement, to fit, and put it up from the cellar through the house floor, just behind the stove, and close to it, where it will be out of the way. Let this enter the stove-pipe by means of an elbow just above the top surface of the stove. Have a damper placed in this pipe near where it enters the stove-pipe, so that you can turn the draft on or off at pleasure. As to the size of this pipe you can have it made from 3 to 6 inches or more in diameter, according to the size of your stove-

pipe. You now have a simple, convenient, and most effective upward ventilator, which is greatly superior to one leading directly outside, for the reason that, in consequence of the draft of the stove, the upward rush of air is greatly increased, and hence a 3-inch ventilator, in such a position, is more effective than one twice as large in the ordinary position. If your cellar is large you can repeat this arrangement in the other stove or stoves standing over the cellar. If you have but one stove standing over your cellar, and are wintering your bees in the cellar, put them directly under the stove where the ventilator will go up from about their centre. If Mr. Mason will adopt this plan of upward cellar ventilation, together with the following method for the ingress of fresh air, I will stake my reputation he will winter his bees successfully in his cellar, even though it have half a dozen springs of water in it. Of course, in cases of wet cellars, the bees must be elevated 2 feet or more from the cellar floor. I have had this arrangement for cellar ventilation in use a dozen years, and am perfectly satisfied of its great superiority over other methods. Although I have an outside bee-house filled in with sawdust, I always, of late years, winter my bees in my cellar, with excellent results. This winter, which has been unusually long and severe, they have now been in winter quarters nearly four months, yet they are still quiet and healthy with the exception of one or two colonies, which were slightly out of order two or three weeks ago. The weather is still, at this writing (March 17), cold and raw, with no prospect of getting bees out to fly for some days yet.

As to under cellar ventilation for the introduction of pure air from without, the subterranean conveyance of the air for some distance to raise its temperature in transit is undoubtedly the best method; but unless this matter has been attended to when the cellar was being built, it is scarcely practicable in most cases. The next best plan then is to introduce the air through a pipe leading from the outside through the cellar door near the bottom, to be also provided with a damper. If there is no door leading from the cellar outside, the pipe may be put through a cellar window; or there may be a little door on hinges put in place of one of the window lights to be opened warm days.

Let every reader of this ventilate his cellar if it is not already done. Let him do it for the sake of his family as well as his bees. At this particular season of the year, cellar air is proverbially impure, and taken into the lungs and blood is disease-producing. We are more careful to guard our bees from disease than ourselves and our families. Let us guard both, but first our families.

I hope that every reader of the BEE JOURNAL, who neglects cellar ventilation, will mark this article and read it again next fall, before he puts his bees in the cellar.

Selby, Ont.

For the American Bee Journal.

Honey Rack for Sections.

H. LANPMAN.

I send to the Museum a sample of my improved comb honey rack, complete. It is very simple, easily adjusted, and cheap. One rack holds 8 sections 5x6 xt³/₄, which are the size I use, and 4 cover a hive. They are put on the hive crosswise. In the spring you can put on one or two tiers of sections or more, as may be desired, by turning the quilt back enough to admit them. In tiering up, one can be set directly on the other, and when they are filled, they are crated for the home market, and are as cheap as anything you can get; and, using them for crates, separators are not needed. When any rack is finished, it can be removed without disturbing the rest. They are made like this: Take 2 pieces of heavy tin, 16 inches long and 1 wide, bend at right angles; cut a 1/2 inch slot in the end, bend so as to make a square corner; now take a piece of wood 1/2 inch thick, 3 wide and 5 long, place it in the corners and nail with small nails. Cut a slot in the tin, 1/2 inch long, 2 1/2 from the end, and a little slanting, so as to run 1/2 inch below the top of the end piece; now, take a piece of tin 1/2 inch wide, put it through the slot, clinch and nail to the end piece. This brace is to stay the top so as to key the sections in. Cut two pieces of glass, the same size as the sections, and place one at each end, and key all together. It would be necessary to watch, in case of damp weather. I have shown it to a number of my brother bee-keepers and they all think it a good thing and will use it.

Rockton, Ill.

[The section rack is not a new one. We have had one of them in our Museum ever since 1877, which was made and used by Mr. O. J. Hetherington, of East Saginaw, Mich., for several years before that. They were mentioned in the BEE JOURNAL at that time, and the engraving used in

this article was the same one then made to describe them, the only difference being the four stays across the corners to strengthen them.—ED.]

For the American Bee Journal.

Bees in Florida vs. Iowa.

O. O. POPPLETON.

I see, by late numbers of the JOURNAL, that our homes in the Northwest are actually surrounded by cold weather, snow, ice, blizzards and

dead bees, but it is hard for us, who happen to be stopping in this far-away corner of the world, to realize that such things can be. Here it is considered extremely cold when the thermometer marks the freezing point; it ranging at present from about 55° in the morning to 80° in the afternoon. Bees are booming; one of my colonies cast a natural swarm Feb. 25, and a second swarm ten days later, filling up their hives with honey and brood, in fact, are in the same condition now that I hope my bees in Iowa will be by the middle of next June.

I am heartily in favor of organizing an Iowa State Bee-Keepers' Association, and should have done what little I could toward that object had I not been so far absent from the State, both last winter and this. The plan of holding the first convention during our next State Fair at Des Moines, seems the most feasible, and I hope some bee-keeper, living in or near that place, will take the responsibility of calling a convention and making the necessary local arrangements.

On page 104, Mr. Demaree says that his bees "rarely ever supersede their queens during the early and late honey harvests." The exact reverse of this has been true in my apiary, nearly all the superseding being done during the late harvest, usually during the month of August. Difference of localities is, of course, the cause of our different experiences.

He says further, on same page, "that he does not remember of ever having had a queen to survive two whole seasons whose wings had been cropped in the usual way." This is also directly contrary to my experience, as I have had scores of them retained through their second and third seasons, and some through their fourth. I do not believe that clipping a queen's wings has a particle to do with their being superseded, or with causing natural swarming.

I have practiced clipping queens' wings for several years past, and have not been able to see a particle of harm result from the practice, but do know that it has been quite a help. I hardly think that mere theoretical reasons will induce me to change my light Italian bees for hybrids, or discontinue clipping queens' wings so long as, by their aid, I can keep my average production of honey away up among the best.

I used to catch queens while clipping their wings, between thumb and forefinger, but have lately used a pair of jeweler's tweezers for that purpose. I think all who give the tweezers a trial will continue their use.

Tampa, Fla., March 12, 1883.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Transferring Bees.

1. In your new method of transferring, how do you unite the second forced swarm with the first one, without danger of their fighting? 2. Will not a good portion of the second driven swarm return to the old gum and be lost? 3. Will not a considerable lot of black or impure drones be let loose from the old gum by the time the second drive is made? Myersville, Md. W. R. YOUNG.

1. I never knew any fighting to take place, because the bees are all of one queen and the second queen is only just out.

2. The "old gum" is split up for kindling, and they, therefore, will hardly find it to return to. The new hive, whether increase is made or not, is practically in the place of the "old gum."

3. Supposing that the old colony is not of the blood you wish, you will have to put up with them, or guage them out, and kill them as fast as they hatch.

Questions.

1. Will it do to arrange supers with sections at right angles with the brood frames, or ought they to run parallel? 2. What space ought to intervene between brood frames and the sections? 3. What point must the temperature reach to make it safe to lift brood frames and examine them? 4. I find by measuring, that sections purporting to be 2 inches wide are only 1½ wide. Is this the rule, or are they meant to be 2 inches? 5. My brood frames are made of plain, flat pieces, without rib or wire on top bar, 10x11½ inside measure. How shall I fasten foundation in them? 6. Is it proper to put full sheets of foundation in frames, of the above size and shape? 7. What foundation do you prefer? Northboro, Iowa. O. E. MOORE.

1. For convenience in handling, and the position of hives, and getting straight combs, I much prefer to have all combs run parallel.

2. 5-16ths where there is no honey board between them. Where there is, the same between the board and each.

3. That depends entirely on how long you keep them out. I handle them any time when the bees can fly, and often, quickly, when they cannot.

4. They are usually scant 2 inches. Thinner combs are best to produce.

5. I should wire them with No. 30 tinned wire. If I only wished to put on foundation guides 1 or 2 inches wide, I would see that the under side

of the top bar was dressed smooth, and "mash" on with putty knife, or Parker foundation fastener.

6. Most assuredly; and I should be sure to do it, but not without the use of wires.

7. Given, Vandervort, Dunham and Root, and, in fact, all kinds are worth more than \$1 per lb. to any one who will use them properly. I have had the best success with the Given, both for brood and surplus departments.

SELECTIONS FROM OUR LETTER BOX

Making Comb Foundation.

I packed 6 colonies of bees with chaff and straw, in clamps, and they did not have a cleansing flight from the last of November until the middle of February, but they have come through, so far, all right; less than two teacupfuls of bees have died, in all of them. Please describe the utensils necessary to make foundation with a roller mill. T. J. PIGG.

Riverside, Iowa.

[The necessary utensils for making comb foundation, and their use, (with other useful hints), are thus described by a manufacturer:

Make the dipping tank 4x12 in., and 2 feet deep; set it in a larger one, with water between, to regulate the temperature. Melt your wax in another boiler (a common wash boiler will do), have water in, to prevent burning the wax; dip into the deep tank as fast as the wax is melted.

Make 4 or 5 thin boards of seasoned basswood, the exact width, when dry, that you want your sheets. Nail cleats on top, to prevent warping, and make a handle. Have them thoroughly water-soaked before using; the boards will swell as much as the sheets will shrink. Wet the boards before dipping, but shake off all the water you can. Put the board in the wax as deep as the length you want your sheet, repeat as soon as the wax stops dropping, dip 3 times for brood foundation and once for boxes; hold the board perfectly plumb while cooling; as soon as the wax stops dropping after the last dip, set it to one side and take another board. By the time you have dipped four, the first will be ready to peel off. If the boards are smooth and edges perfectly square, your sheets will need no trimming. When the wax begins to scum around the edges of the tank, the temperature is right. If sheets crack in cooling, your wax is too hot. By the above plan the sheets will be tapering. If started with the thin end of the sheet in the mill, you will never have no trouble, and the sheet will be long enough to cut off the thin end.

Thin paste made of cheap starch makes the best lubricator for the rolls.

Dipping plates, as described above, made from clear straight-grained basswood, for any width, costs about 3 cents per inch in width. If your tank is wide enough to take a 12-inch dipping-board, you can dip narrow strips for starters, 6 at a time, by having a similar board divided into 3 parts, by broad saw-cuts. Each board will then be about 3¾ inches, and every dipping makes 6 narrow sheets.

The manufacturers furnish directions for using when you buy a machine, mill or press.—ED.]

A Section too Small.

MR. EDITOR:—You will remember, when we were at Toledo, at the Tri-State Fair, among a crowd of beekeepers, I stated that "the one-pound section was a curse to the producer, a curse to the retailer, and a curse to the consumer," and gave my reasons. The sneering, silent laugh pronounced me the fool of the crowd. At the Michigan convention, I stated the same thing, with the same decision. Now, comes Mr. F. I. Sage, of Wethersfield, Conn. (who handles over 50 tons of honey a year), with an article verifying my statement fully, and Mr. Wright, of Knowersville, N. Y., too, must be reckoned with us. I write this to remind the readers of the BEE JOURNAL that I am not the only foolish one left.

E. B. SOUTHWICK.

Mendon, Mich., March 16, 1883.

Large Yields of Honey and Increase.

When I see reports of large yields of honey and great increase of bees, I always know what I think of it. I think, or rather know the party making said report, has had a good, long, regular flow of honey. In his book—"The Hive and Honey Bee."—Rev. L. L. Langstroth says that a large increase of bees and a large yield of honey cannot be had at the same time, and I am satisfied if the dear old man is spared to revise that classic bee book, you will find this statement corrected, for he has too much faith in his fellow bee-keepers to think they would intentionally tell a bee yarn about it. If the good old man could be in my bee-yard, this beautiful Sabbath morning, he would exclaim, no wonder Texas rolls up such big reports! My bees are fairly crazy over the cottonwood, Judas tree, wild plum, fruit trees, and a host of other blooms. One continual bloom from now until July, if we can only have a good shower of rain every 15 days.

B. F. CARROLL.

Dresden, Texas, March 20, 1883.

Feeding Flour in Spring.

1. What is best for early feeding in the spring? 2. How should it be given? P. REARDON.

Jamestown, Colo.

[You will find an excellent article on this subject in this number of the BEE JOURNAL.—ED.]

Failures Through Mismanagement.

It is stated here by a man who professes a practical experience, that bees cannot do well here, because the pasturage is grazed too close. My experience is exceedingly limited, but in no book or bee paper have I ever seen such a statement. There is an abundance of poplar, ash, locust, and other bee trees here, plenty of white clover, fruit trees and fall plants, and in a radius of 5 miles there are not 100 colonies of bees. I think that a failure is owing to mismanagement. It is true that the meadows here are closely grazed. Can that be the reason that the old-fashioned bee men have so little honey?

E. H. GAITHER.

Harrodsburg, Ky., March 17, 1883.

[Ordinary grazing helps some bee pasturage. Probably mismanagement has as much to do with the lack of honey as anything.—Ed.]

Half-Pound Sections Not Wanted.

This is a cold winter. My bees are packed in sawdust, on the summer stands; they are now in good condition. I lost one colony by dysentery; the rest all clean and bright. Much has been said and written about introducing the consumption of honey in place of syrups, and now some turn around and work on the contrary to make honey a luxury, which it surely is when half-pound sections are adopted. It is not the consumers that demand small sections, but some bee-keepers that do it.

GEORGE CASTELLO.

Saginaw, Mich., March 17, 1883.

Large Increase and Honey Crop.

I am satisfied that if I had read Mr. Heddon's article on "How to prevent after swarms," in time for last season's work, it would have been worth a year's subscription of the BEE JOURNAL to me. Mr. Roberts says on page 137, that he does not believe in large yields of honey and bees in the same season. I have sold 3,600 lbs. of last season's crop, "all the same," and I have 65 colonies alive at present (6 dead), besides what honey a family of ten could use, and there are full 30 lbs. to the colony, at this date, in the hives, besides the 100 extra combs of honey that are reserved for use, if needed, which I doubt. If Mr. Roberts will visit me, this spring, I think I can convince him that "these are facts." All of the honey and increase was produced by 19 colonies, that did not have one pound of sweets in any of them on June 4, 1882, and 3 of them were four-frame nuclei, shipped to me May 1, and transferred May 4. Bees are in fair condition, and healthy at present. S. H. MOSS.

Colchester, Ill., March 16, 1883.

Bees in Good Condition.

After almost 4 months confinement I took 15 colonies out of my cellar on the 13th; all in nice, clean condition, and having plenty of honey and brood. On the day following I took the rest out of the cave; 130 in all, and one dead; the rest were heavy and had

plenty of bees. So, out of 145, 141 came through in as healthy condition as I ever saw them in the spring. I had 16 on the summer stands, with no protection, and lost 4. We have had a pretty severe winter, and a good many bees are lost, where no protection was given them; while others, that were packed in chaff, or put in cellars, came out without much loss, as a rule.

J. E. HASTINGS.

Carlisle, Iowa, March 16, 1883.

Bees Strong and Healthy.

My bees, to all appearances, have wintered splendidly; I put 100 colonies in bee-house, and took out 101 hives, with bees in them. I had a hive of nearly empty comb in the house, and the bees got so hot, the day before I took them out, and crawled around and got into this hive, enough to make a swarm, but, as I had no queen, I had to put the bees in other hives again. I fear the effects of the sudden change on the 18th; the bees were flying out pretty freely, when a gale struck us from the northeast and it began to freeze; the bees were scattered, and I fear there is a large loss to each hive by their getting chilled. I never had my bees come through as strong and healthy, when taken out, as they were this spring; but I expect to lose some that I will have to break up, by loss of queens, as I did not get all my old queens changed last fall.

R. R. MURPHY.

Garden Plain, Ill., March 21, 1883.

Shipping Crates for Honey.

What size of shipping crates is the most popular in the great honey markets of the United States?

M. BLANCHARD.

Sherwood, Wis.

[Those holding one dozen two-pound sections or two dozen one-pound sections of honey.—Ed.]

Gathering Pollen and Honey.

Bees came through the winter finely; have plenty of honey yet; are breeding up rapidly, gathering pollen and honey from peach and plum blooms. We have splendid weather, and all early vegetables are up and growing finely. I have 40 colonies to start with.

E. P. MASSEY.

Waco, Texas, March 14, 1883.

Looking for a Good Honey Harvest.

It has been a very poor winter for bees here, they have had no flight since Nov. 11, worth mentioning. Dysentery is prevailing here, which seems to be caused by bad honey gathered last fall; some that were fed with sugar are not affected. I have 8 colonies in chaff hives, and packed 63 in a chaff bin; those in the bin had the dysentery, and some, I fear, are passed their troubles. The loss around here will be very heavy, this spring. We are looking for a good honey harvest, as we always have a good one after a hard winter and lots of snow. My bees are all Italians and Syrians. I use the Gallup frame, but have two in the

Quinby frame, which is far stronger than the rest, and always winter and come through stronger than the rest. Honey sold readily at 15c. per lb. for extracted and 25c. per lb. for comb. I believe dampness is worse on bees than cold. I could not get along without the BEE JOURNAL.

ARTHUR RUSSELL.

Millbrook, Ont., March 14, 1883.

Corrections.

I find some blunders in my article on the standard Langstroth hive, on page 116 of the JOURNAL, which I desire to correct, to wit: The figures 183 $\frac{1}{2}$ and 185 $\frac{1}{2}$, given in 3d and 4th lines, should be 17 $\frac{3}{8}$ and 17 $\frac{5}{8}$ —one inch out of the way, in that place, might make lots of trouble. In line 35, next column, drop first comma and "hives," and insert *mills* instead. The word "former" in 36th line should be *farmer*.

M. M. BALDRIDGE.

St. Charles, Ill.

[The "blunders" in the figures were in Mr. B.'s copy; the words were not very plainly written and were an oversight of the printer, who also omitted a figure "4," in Mr. B.'s article on page 102, in the second line after the last engraving. It should read: "the 4 recesses or passage ways."—Ed.]

Bees in Georgia.

Bees that have been properly cared for have, thus far, wintered well in Cherokee, Ga. The honey flow was light, in this section, during the latter part of last summer; hence, many late colonies, that were not fed, died of starvation. Bees are invariably wintered upon their summer stands, in the Southern States, and if kept dry, with plenty of good, available food, are never seriously affected by cold. It would seem that the above conditions are all that need be observed in any honey-producing country, since to suppose that bees freeze and die under such circumstances, is to suppose a physical inconsistency contrary to the laws of nature. Our bees have been gathering pollen for the past three weeks.

WM. FARELL.

Rome, Ga., March 9, 1883.

Out of the Woods Again.

The middle of March has come, and my bees are all alive but two nuclei, which died of starvation. My bees have been bringing in pollen for a month from the elm, and have from 1 to 3 frames of brood in each hive. I consider that good for the middle of March. In answer to the question asked by Mr. C. W. McKown in the BEE JOURNAL for March 7, I would say I have a few chaff hives, but my bees are in no better condition in those than in my single-walled hives. I do not want any more chaff hives in my yard; they are too unhandy for transportation and are more expensive than single hives. I place my hives in a row and pack sawdust all around them, except the front, and cover them well. My thermometer reached zero

only twice last winter, and I do not want any better hive than the single-walled Langstroth hive for this part of the country. J. F. KIGHT.

Poseyville, Ind., March 15, 1883.

Bees Carrying in Flour Lively.

Our bees are booming. We have 88 colonies. They are rearing young bees very fast. They have carried in nearly 200 lbs of flour. C. J. LOHMANN.

Cameron, Mo., March 19, 1883.

Substitute for Pollen.

Corn meal is the best I have tried yet. If you want to see bees circling, just take 3 or 4 cotton grain sacks, spread them on some boards, and lay bricks on the corners, to keep the wind from blowing them off; now spread the meal on them. Just try it. Bees are working on soft maples, today. My 30 colonies wintered all right, and all have hatching brood.

J. S. HOFFMAN.

Madisonville, O., March 19, 1883.

Bees packed in sawdust wintered well.

I packed 40 colonies, on the summer stands, in sawdust; they appear to be in good condition, so far. I have 16 colonies in a summer and winter house. Those on the north side show signs of dysentery; those on the south side seem to be in good condition. The weather has been very cold this winter, and now it is 5° above zero; on the 20th it was down to 5° below.

J. N. BECKER.

Oakfield Centre, Mich., Mar. 22, 1883.

Blasted Hopes.

140 days, and not a day in which I could set a colony out. I had 44 in fine condition, on Nov. 5, 1882, and today I have only 12 left; there is from 2 to 4 feet of snow all over my yard, and the mercury was down to 11° below zero last night, and is 10° below to-night. "Blasted Hopes," sure enough, for 44 colonies of as handsome bees as ever flew. Discouraged, is no name for it; but as Adam Grimm said, "If I do lose all, I will show you how soon I can fill those hives up again, with so many good combs as I have." Nearly all the bees around here are dead.

C. F. GREENING.

Grand Meadow, Minn., Mar. 20, 1883.

Convention Notices.

These semi-annual meeting of the Western Michigan Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to beekeepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, Sec.

Kansas City, Mo.

J. A. NELSON, Pres. Wyandotte, Kas.

The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, Sec.

Coopersville, Mich.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.

Kingston, Texas.

The next meeting of the Haldimand, Ont., Bee-Keepers' Association will be held at Nells's Corners on Saturday, March 31, 1883, at 11 a. m.

H. CAMPBELL.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

The regular meeting of the Farmers' and Gardeners' Club, will be held April 2, at A. Z. Madison's office, Fredonia, N. Y. Question: "Bees, Fish and Poultry." Mr. U. E. Dodge will open the discussion with a lecture on "Bees and Bee-Culture," giving practical manipulations of the hive, showing the various improved implements, devices and terms used in bee-culture, illustrating the lecture with a colony of bees. Bee-keepers are especially invited to spend the afternoon at Sunshine Apiary, where Mr. Dodge will try and entertain them. Mr. Dodge is a thoroughly practical apiarist, and this will be a rare treat for bee-keepers in Western New York. Means will be taken to form a Bee-Keepers' Association for this part of the State.

A. Z. MADISON, Sec.

U. E. DODGE, Pres.

The Eastern Michigan Bee-Keepers' Society, will hold its annual meeting in Detroit, April 3, in Abstract Hall, commencing at 10 a. m. The following subjects will be brought up for discussion: What is the best means of extending the honey market? At what price can honey, either comb or extracted, be afforded? Is there danger of over-production? Has glucose affected your market, and if so, how? What is the best test for glucose? In judging queens, what points are to be considered, and what is the order of their importance? Foul brood, and its prevention and cure. An interesting meeting is expected.

A. B. WEED, Sec.

75 Bagg St., Detroit, Mich.

The spring meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, Sec.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address; Essays: Prof. A. J. Cook, on Wintering Bees; S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. WOOD, Sec.

North Lansing, Mich.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., March 26, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12c. on arrival.

BEESWAX—Comes in slowly and brings 20c. per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 16c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12c. to 14c. Extracted, 8c. to 10c., according to color.

BEESWAX—None in the market.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Quotations for choice are merely nominal, as there are none of that quality offering. Common qualities are in light supply and still lighter demand.

White comb, 14c. to 17c.; dark to good, 11c. to 13c.; extracted, choice to extra white, 8c. to 9c.; dark and candied, 5c. to 7c.

BEESWAX—We quote 30c. to 33c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14c. to 16c.—some inferior sold at 10c.; strained at 6c. to 7c.; extracted at 7c. to 8c.; lots in small packages more.

BEESWAX—Source and wanted at 33c. to 34c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18c. to 19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17c. to 18c. Extracted very dull at 9c. to 11c.

BEESWAX—None in market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22c. to 25c.; 2 lb. sections, 20c. to 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

And still, we are obliged to say that the books on Queen-Rearing, by Henry Alley, have not been received. As soon as they do, the orders we have on hand will be filled. In order to appease those who are impatient, we may say that Mr. Alley has written us that the book will make 25 or 30 more pages than he anticipated; and adds: "We had no idea that there would be so many pages. I think all will be well pleased with the extra amount, and feel compensated for long and patient waiting." It is all right, except announcing it "ready for delivery" a month before it is *actually printed and bound*. As this is Mr. Alley's first experience in publishing, we shall have to overlook it on the ground of inexperience. Old publishers know better.

The stylographic pen is one of the necessities of our modern civilization. If Hood's song had been "Dip, dip, dip," instead of "Stitch, stitch, stitch," it would have lost its text at the hands of Mr. Livermore, who has given his age this perfection of pen, penholder, and case, and ink, all in one, handsome, and always at hand and ready for use. The inventor has put some new improvements into it, and now what remains but for every scribe and letter writer to find it on his desk. Ink, filler and cleaner, all go with it. And, to crown all, the price has been reduced to \$2. Send that amount to the sole agent, Mr. Louis E. Dunlap, 290 Washington St., Boston, Mass., and the return mail will bring you this most perfect pen.—Contributor, Boston, Mass.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

WOOD SEPARATORS!

PRICE LIST of the Besse Wood Separators:
For the wide Langstroth frame, per 100, 50c.; per 1000, \$4.00. They are of basswood, size 17"x 32"x 16. Any size to order. Send 3 cent stamp for sample.

OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

VOL. XIX.

CHICAGO, ILL., APRIL 4, 1883.

No. 14.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Eyes of a Bee.

A correspondent, who had read our brief reply to Mr. C Theilmann on this subject, sends the following request:

MR. EDITOR:—Please describe more fully, in detail, the simple and compound eyes of the bee. It is a subject of interest to us, who do not understand all about bee optics. Tell us what simple and compound eyes are, in the BEE JOURNAL. J. W. B.

Swanee, Ga., March 10, 1883.

We cannot do better than to quote, from Prof. Cook's "Manual of the Apiary," the following, on this very interesting subject:

"The eyes are of two kinds, the compound, which are always present in mature insects, and the ocelli or simple eyes, which may or may not be present. When present there are usually three, which, if we join by lines, we will describe a triangle, in the vertices of whose angles are the ocelli. Rarely there are but two ocelli, and very rarely but one.

"The simple eyes (*F F F*) are circular, and possess a cornea, lens and retina, which receives the nerve of sight.

"From the experiments of Reaumur and Swammerdam, which consisted in covering the eyes with varnish, they concluded that vision with these simple eyes is very indistinct, though by them the insect can distinguish light. Some have thought that these simple eyes were for vision at slight distances. Larvæ, like spiders and myriapods, have only simple eyes.

"The compound eyes are simply a cluster of simple eyes, are situated one on either side of the head, and vary much in form and size. Between or below these are inserted the antennæ. Sometimes these last are inserted in a notch of the eyes, and in a few cases actually divide each eye into two eyes.

"The eyes may meet above as in drones (Fig. 1), most two-wing flies and dragon-flies, or they may be considerably separated, as in the worker-

Fig. 1.—Head of Drone, magnified.

bees (Fig. 2). The separate facets or simple eyes, of each compound eye, are hexagonal, or six-sided, and in the microscope look not unlike a section of honey-comb. The number of these is prodigious—Leeuwenhoek actually counted 12,000 in the eye of a dragon-fly—while some butterflies have over 17,000. The compound eyes are motionless, but from their size and sub-spherical shape, they give quite a range of vision. It is not likely that

Fig. 2.—Head of Worker Bee, magnified.

they are capable of adjustment to accord with different distances, and it has been supposed, from the direct darting flight of bees to their hives, and the awkward work they make in finding a hive when moved only for a short distance, that these eyes are best suited to long vision.

"Sir John Lubbock has proved, by some interesting experiments with strips of colored paper, that bees can distinguish colors. Honey was placed on a blue strip, beside several others of various colors. In the absence of the bees he changed the position of

this strip, and upon their return the bees went to the blue strip rather than to the old position. Our practical apiarists have long been aware of this fact, and have conformed their practice to the knowledge, in giving a variety of colors to their hives. Apiarists have frequently noted that bees have a rare faculty of marking positions, but, for slight distances, their sense of color will correct mistakes which would occur if position alone was guide."

Our correspondent should get a copy of the Manual. Its perusal will repay him a hundredfold its cost, as well as be a ready book of reference on every subject connected with bees.

Clubbing with Cook's Manual.—A subscriber, who has already paid \$2.00 for the Weekly BEE JOURNAL for 1883, wants to know if we will send a copy of Cook's Manual or Bee-Keepers' Guide, in cloth, if he sends us 75 cents more. Certainly, we will; the only requirement being that the full price for the JOURNAL, either weekly or Monthly, has already been paid to us, and no other premium has already been sent. All such may send us 75 cents in postage stamps and get the Manual, bound in cloth, by next mail.

The Manual, bound in paper covers, will be sent for 50 cents, extra to the price of subscription. This offer will be good only until the seventh edition, printed last year (1882), is exhausted, and no more will be printed in paper covers. This offer will, therefore, only last for a very short time, and those who wish to avail themselves of it, should order at once.

Some persons, having sent us a club of subscribers through a club-agency, have written us to send the premium for getting up the club. To do this would be doubling our premium. The club agency gets their commission, and then we can send no premium. Please remember, to be entitled to the premiums we offer, the full amount of the subscriptions must be sent direct to this office.

CORRESPONDENCE

For the American Bee Journal.

Reply to J. W. Merrifield.

G. M. DOOLITTLE.

On page 100, present volume of the BEE JOURNAL, J. W. Merrifield asks why the plan of giving each colony a laying queen immediately after swarming, had not proven a success with me. That is right. If you do not understand anything, ask questions, and I will explain, if I know how; if I do not, I will frankly say so.

For years, we have been told that no colony should go without a laying queen a single day, if it were possible to give them one, and plans of introducing queens, which required that the hive should be queenless a few days previous, have been severely criticised. We have also been told, for years, that the bee-keeper who wished to secure the best results from his bees, should have a laying queen ready to give each old colony as soon as they swarmed, as the time lost to them, by rearing a queen, was equivalent to a swarm of bees. Being eager to know, for myself, all the plans which would give the best results, I have experimented largely, and the truth of the statement that the time lost to the bees by rearing a queen in natural swarming, was equivalent to a swarm of bees, is the first reason it has not proven a success. If it were bees I was after, the case would be different. With me, white clover yields enough honey to keep the bees breeding nicely, and prepares them so that they mainly swarm from June 20 to July 1. Our honey harvest is from basswood, which blooms from July 10 to 16. Now, all who are familiar with natural swarming, know that the bees are comparatively few in numbers in spring, and increase by the rapidly increasing brood produced by the queen, which, in due time, hatch into bees, until a swarm is the result.

By giving a laying queen to a colony immediately after it has cast a swarm, we bring about the same result (swarming) as before, for we place the bees in the same condition. The only difference is, that having plenty of brood, they build up quicker, and are prepared to swarm in a shorter time. As this second swarming, brought about by giving the laying queen, comes right in our basswood honey harvest, it cuts off the surplus honey, for it is well known that bees, having the swarming fever, do little or no work in the section boxes, and if allowed to swarm, the object we have sought after (section honey) is beyond our reach.

Having given the result of my experience on this point, let us look at how the same colony would work, had we not given the bees a laying queen. Eight days after the swarm has issued, the first young queen will have emerged from her cell, as a rule, when

the apiarist should remove all the other queen-cells from the hive, so that second swarming is entirely prevented. In ten days more our young queen is ready to lay, which is about the time the basswood begins to yield honey largely. During this period, between the time the swarm issued and the young queen commences to lay, the bees not having any brood to nurse for the last half of the time, consume but little honey; hence, as fast as the young bees emerge from the cells, they are filled with honey; for bees, not having a laying queen, seldom build comb in the sections. Thus, when the young queen is ready to lay, she finds every available cell stored with well-ripened honey. At this point, the instinct of the bees teach them that they must have brood or they will soon cease to exist as a colony, and a general rush is made for the sections, the honey from below is carried above, so as to give the queen room, and, in a week, we have, as a result, the sections nearly filled with honey. I have often had such colonies fill and complete 30 two-pound sections in from 8 to 12 days, while those to which I had given the laying queen immediately after swarming, did little but swarm during the same time.

Bear in mind we are talking about producing comb honey, not extracted. Different locations may give different results, still I think that nearly all sections give a large flow of honey at a certain period during the season, rather than a steady, continuous honey harvest the whole season. To such sections these remarks are especially applicable.

My second reason is, that after basswood we have a honey dearth, hence, the bees from the introduced queen are of no value, but, on the contrary, become consumers. On an average, it takes 21 days from the time the egg is laid, to the perfect bee ready to emerge from the cell. Then, if the colony is in a normal condition, this bee does not commence labor in the field till 16 days old; hence, the eggs for the honey-gathering bees must be deposited in the cell 37 days before the honey harvest ends, or else they are of no value as honey-producers. As the basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat and fall flowers yield honey, it will be seen that a great gain is made by letting each old colony, having cast a swarm, rear their own queen, for, thereby, we save the expensive feeding of the larvæ, which are to become expensive consumers of the honey of the hive. Also, the chances are, that when the colony rears its own queen, they will be stocked with younger bees for wintering in November, than where a queen was introduced immediately after swarming.

The one point worth knowing above all others in bee-keeping, is a thorough knowledge of the location we are in, as to its honey resource, and then getting the largest amount of bees possible at that or those times to

gather the honey, having just as few at all other times as is consistent with the accomplishing of this object. A prominent apiarist advised, a few years ago, using artificial heat to get our bees strong so that they would swarm in April, while others, like L. C. Root, was advising keeping them in the cellar till pollen was plenty, to prevent early and useless brood-rearing. The advice of the first would be to bee-keepers the same as my sending four men and teams 12 miles to the railroad for a car load of lumber when I did not know it was there for certain. They went and came back, but no lumber. The part which particularly had a bearing on me was, I had to pay them the same as if they had found the lumber and brought it back. Just so with getting bees out of season. We have to pay the same price for them that we would to get them, so that each one became a producer instead of a consumer.

If all who read this article will study their location, and then rear their bees in reference to that location, I think they will find their bees will do as well as their more successful neighbors.

Borodino, N. Y.

For the American Bee Journal.

Wintering, Ventilation, Etc.

DR. I. P. WILSON.

DEAR EDITOR:—After spending an hour very pleasantly in reading the JOURNAL, I desire to say that the extracts you have published from Mr. Baldrige's letters are quite sufficient to convince any candid mind that *right* is not on his side. Yes, your readers, "certainly," will approve of the controversy being terminated right here. The columns of the JOURNAL are too valuable to be occupied with such wrangling.

My bees have wintered tolerably well. I had 80 colonies last fall, and, for the first time for many years, I left all but 12 colonies on their summer stands. One of the 12 placed in the cellar, died of diarrhoea, and 8 of those left out died of the same disease, while 3 colonies starved.

For a number of years I have made a practice of ventilating each colony so that a circulation of air can be had through the hive. Those that died of diarrhoea were not so ventilated. My method of ventilation is as follows: The cap on top of the hive has two auger holes, covered with wire screen, directly opposite each other. The strip covering the front (or back) opening in the honey-board is left off. The entrance of the hive may be left entirely or partly open. Thus they are ventilated through the entire winter. When it is warm enough for the bees to commence flying in the spring, the honey-board should be closed. The circulation of the bees will cause a circulation of the air. If an inch auger hole is made a little above the centre of the front of the hive, I do not find it necessary to leave the honey-board open. I refer now to bees left on their summer stands.

A number of years ago, I had one of my apiaries in the country. I went out late in the fall to prepare them for winter. The only ventilation I intended to give them was through the entrance to the hive. I accidentally left the honey-board open in one hive, after taking off the surplus boxes, also left the entrance entirely open, and, in addition to this, there was an auger hole in the centre of the front of the hive. I did not visit the apiary again until spring. To my surprise, the hive I had accidentally left open was in, by far, the best condition of any of them; the comb being clean and free from mold, and scarcely any of the bees dead. The others were all, more or less, moldy; about one-third of the bees were dead, and all in a filthy condition. Since then, I have been more particular about ventilation, and have had much better results.

Experience has taught me another thing, and the 3 colonies that died from starvation, last winter, is only a repetition of my experience on former occasions. There were supplies in the hive, but the bees could not reach them. In the fall, the brood, and, consequently, the cluster of bees, were in the centre of the hive. The outside frames were filled with capped honey. As the winter advances the bees shift their location to one side or the other, and in doing so they leave large supplies behind them, and when they have exhausted the honey on one side of the hive, they are too far from the bountiful supply on the other, to reach it during the cold winter.

The lesson to be learned, then, is this: The brood should be transferred in the fall from the centre of the hive to one side, and then their supplies will be accessible to them. I find it pays well, at this time (in the fall), to cut a small hole in the centre of each comb, that the bees may pass through, and not be compelled to pass around the frame.

Burlington, Iowa.

Colorado State Convention.

[Mr. Phil. Reardon, Jamestown, Colo., has sent us a report of the convention held at Denver, Colo., March 15, from which we make the following extracts.—Ed.]

In the absence of Mr. D. S. Grimes, the president of the Association, Mr. DeVinney called the meeting to order at 10 a. m. The morning session was informal.

Dr. Godfrey gave his experience in the care of bees. Among other things he spoke of the quietness of motion necessary. These insects hated quick motions, and the least betrayal of nervousness or fear, on the part of the keeper, would cause a disposition in the bees to sting the attendant, and it would be impossible for him to go near them. Kindness and gentleness, on the other hand, had a reciprocal effect on the inmates of the hives, and one could go among them and handle them without molestation.

The afternoon session convened at 2 o'clock, with Mr. D. S. Grimes, the

president, in the chair. The election of officers resulted as follows: For President, Dr. Godfrey; Vice-President, E. Millison; Secretary, J. L. Peabody; Treasurer, Mrs. O. Wright.

A committee, consisting of the president, vice-president and secretary, was appointed to draft a new constitution and by-laws, the old regulations having been lost in the departure of the former secretary for California.

A resolution, to incorporate the Association under the laws of Colorado, was unanimously carried.

It was also decided that the bee-keepers, in connection with the Horticultural Society, should have an exhibit at the National Mining Exposition next summer.

An adoption of a motion then followed to the effect, that under the re-organization of the Association the fees of the old members, which were \$1 a year, should be considered as paid, as the future tax of the Society will only be 50 cents per annum.

Mr. Peabody was appointed to confer with the Horticultural Society regarding a suitable exhibit of honey at the Colorado Exhibition, in August.

Mr. Millison said, at one time the people preferred imported honey to honey obtained from the Rocky Mountain bee plant, found so abundantly in Colorado. Time, however, had reversed the choice, and now the article obtained in this State was richer and purer than that found in any other part of the country. It was only now that people in Colorado were waking up to the fact that such excellent bee-food existed in the State. Something which might be cultivated more than it is here, was sweet clover. Under the influences of the climate it could not be surpassed for honey. Buckwheat, the gooseberry blossoms, wheat and oat bloom were fair, but did not do so well in the West as in the East.

Another member suggested that a wonderful thing about bee-food in Colorado consisted in a more flourishing existence in alkali soil than in other kinds of earth. Although irrigation was necessary for perfect growth, it was not needed so much in the cultivation of clover or other bee-food, as in the East, where a plant would dry up, from want of constant watering. Clover could also be sown at any time. A very curious and wonderful phenomena in Colorado was the honey dew, found on the leaves, branches and stalks of the box-elder, maple, and, especially, the cottonwood. Moisture, brought to bear on the dew, had a strange effect in bringing bees to the tree for food.

Some explained the origin of the dew to the kind of insect, which, by its pecking, brought the juice of the tree all over the leaves and stalks, and some asserted the fact was due to a certain influence of the atmosphere in bringing fluid deposits from other shrubs and plants. This honey dew was found on every tree in a greater or less quantity, and under proper conditions formed an excellent bee-food. Taking it altogether, no State in the Union equalled Colorado as a region for successful bee-culture.

A resolution to prepare a herbarium of bee-food, for exhibition next summer, and for permanent reference, was carried.

A motion was also carried to elect the president of the State Agricultural Society to honorary membership.

The secretary then read a list of colonies of bees, owned by members, with a comparison of colonies last fall and this spring:

"The Worst Kind of Advice."

DR. G. L. TINKER.

Hazardous language that, for a little friendly criticism. But Mr. Heddon proclaims it, and, as a matter of course, he is infallible on things appertaining to the honey bee!

Mr. Heddon cannot mean that his experiment "settles it," that a rack of the thin sections may not be set down on the brood frames and made a practical procedure? For it was not the same as the advice given, see page 151. Then, again, is it not strange that in his "experiment" the sections were glued to the bars of the rack so solid as to be removed with difficulty, with stings and dismay, when other bee-keepers have been, for years, taking off sections without trouble from racks having bars the width of the bottom piece of the sections?

But stranger still, Mr. H. found that the bees did not enter the sections "more readily" by direct passage-ways than "through a honey-board and two shallow air-chambers." His conclusion on this point, as on several others, looks "to a man up a tree" very like an argument for (if not an advertisement of) Mr. Heddon's "case or super method."

I have a number of hives now made on which to test the half-pound sections. To prevent soiling the tops of the sections, and to keep the racks perfectly clean, I shall use a permanent rack on the frames, to be left on during the honey flow, but which may be easily removed at any time if the frames on which it rests are straight and true on top as they should be. As Mr. Heddon did not make it clear whether the supposed difficulty he alluded to was in removing the sections as stated, or in taking off the rack, will he undertake to explain again?

Concerning the use of section racks in connection with a permanent rack, a noted bee-keeper, who has had large experience with the half-pound section, writes as follows: "It is the fastest, easiest and simplest way of handling comb honey we have ever seen."

By the plan advised, the shallow spaces usually allowed beneath the sections of from 40 to 60 cubic inches, that, in any case, must be constantly filled with idle bees before and after the sections are occupied, can be dispensed with and an undoubted advantage secured in obtaining surplus in the small sections. Yet, Mr. H. condemns the procedure, which looks to a larger, cheaper and more attractive production of comb honey, as "the worst kind of advice."

Finally, Mr. H. calls for the "apiarist who now adjusts his sections as advised." There are quite a number who practice a similar measure; among others, Mr. A. G. Hill, who places a row of sections "directly on the frames, saving the expense of a honey rack." Mr. Heddon can now send for that "missionary." There may be a prospect that he be not only reclaimed from infidelic doctrines, but that he may be able to place a higher value on that good old precept, "First cast out the beam from thine own eye, then thou shalt see clearly to cast the mote out of thy brother's eye."

New Philadelphia, O.

For the American Bee Journal.

How I Wintered My Bees.

F. A. BOHL.

I wintered my bees in the cellar on the following plan: My cellar is perfectly dark and well ventilated. I raise my hives off bottom boards, but not enough to let in the mice. I keep a barrel with ice, in the cellar. I took my bees out, on Feb. 28, and lost less than ever before, as I put a fresh lot of ice in the cellar the night before, which kept them quiet, and they did not come out and perish as usual.

I use the Gallup hive, 12x18 inches, inside measure, containing 12 Gallup frames, 10x11½ inches. I use honey-boards on top of frames, leaving about one-half inch space between them and the frames.

I have never used cloths on top of frames, as I can see no advantage in them; if there is any advantage in them, I wish some one would mention it in the BEE JOURNAL.

I obtained 1,100 lbs. of honey, last summer, from 17 colonies, spring count, besides increasing to 38.

My colonies are all stronger in bees now than they were in the fall. The hives are full of honey yet, and I intend to extract it as soon as the weather is fitting.

One swarm came out on Aug. 26, which filled its hive, and is as heavy as a man can carry now. One swarm came out, on June 15, which filled its box and yielded 100 lbs. of nice comb honey. I thought that was a large yield, but it does not compare with some reports in the BEE JOURNAL.

I intend to use sections, this summer, and sow alsike and sweet clover, as bee pasturage. I consider them the best for honey production.

Summum, Ill., March 8, 1883.

Honey and Bee Show at Toledo.

DR. A. B. MASON.

DEAR JOURNAL:—I have just been throwing up my old hat and giving the regulation number of cheers, etc., ("in my mind.") for the officers of the Tri-State (Ohio, Michigan and Indiana) Fair Association, because they have adopted the following premium list for the bee and honey department, to be awarded at the next Tri-State Fair, to be held at Toledo, O., commencing September 10, 1883, and continuing one week.

BEEES, HONEY, ETC.

DR. A. B. MASON, Superintendent.

ENTRIES IN THIS DEPARTMENT ARE FREE TO ALL.

	1st	2d
	Pr.	Pr.
Display comb honey in most marketable shape, product of 1 apiary in 1883.....	\$10	\$5
Display extracted honey in most marketable shape, product of 1 apiary in 1883.....	10	5
Display comb honey in most marketable shape, by a lady, product of her own apiary in 1883.....	5	3
Display extracted honey in most marketable shape, by a lady, product of her own apiary in 1883.....	5	3
Comb honey, not less than 20 lbs., quality to govern.....	4	2
Extracted honey, not less than 20 lbs., quality to govern.....	4	2
Crate comb honey, not less than 20 lbs., in best shape for shipping and retailing.....	4	2
Colony of bees.....	5	3
Colony of Italian bees.....	5	3
Colony of Syrian bees.....	5	3
Colonies of bees must be the property of one queen, and exhibited in such shape as to be readily seen on two sides. Purity of race, docility, size of bees, and numerical strength to be considered.		
Display of queens, to be put up in such shape as to be readily seen by visitors (black not to compete).....	\$3	\$2
Greatest variety of queens put up in same shape as for display of queens.....	3	2
Queens and colonies cannot compete for more than one premium.		
Bee hive, for all purposes, in the apiary, may be represented by model, not less than half size.....	\$3	\$2 00
Bee-hive, glass.....	2	1 00
Wax extractor.....	2	1 00
Honey extractor.....	2	1 00
Foundation mill.....	5	3 00
Foundation press.....	5	3 00
Beeswax, not less than 10 lbs.....	2	1 00
Comb foundation for brood chamber, not less than 5 lbs.....	2	1 00
Comb foundation for surplus honey, not less than 3 lbs.....	2	1 00
Comb foundation machine, making best foundation for brood chamber, on the grounds.....	8	4 00
One-piece sections, not less than 50.....	1	50
Dovetailed sections, not less than 50.....	1	50
Package, with labels, for retailing extracted honey.....	1	50
Bee smoker.....	1	50
Honey knife.....	1	50
Package, for shipping extracted honey in bulk.....	1	50
Machine for making holes in frames for wiring.....	2	1 00
Machines for wiring frames.....	2	1 00
Display of apiary supplies.....	3	1 00
Queens preserved with honey.....	2	1 00
Peaches preserved with honey.....	2	1 00
Apples preserved with honey.....	2	1 00
Pears preserved with honey.....	2	1 00
Largest and best collection of bee literature.....	2	1 00
Largest and best display of honey-bearing plants, properly named and labeled.....	10	5 00
Queen cage, such as is admitted to the mails by the postal laws.....	1	50
Honey vinegar, not less than 1 gallon.....	2	1 00
Honey cakes, with recipe for making.....	4	2 00

Last year, the amount of our premium list was \$100, and this year it amounts to \$208.50. The officers of the Fair association were so well pleased with our exhibit last year, that they adopted this list (prepared and "staid by," by the committee ap-

pointed by the Tri-State Bee-Keepers' Association) without a dissenting vote. They have also granted all exhibitors in our department the privilege of selling anything they may wish belonging to our specialty and in any quantity.

The Fair association offered to put up a building on purpose for our department, but the committee "declined the honor," believing it better to have our department among other appropriate exhibits, where the people are sure to go by thousands, than in a building by itself, where but few would go. We expect to have one or more tents on the grounds for the accommodation of such bee-keepers as come from a distance, and want to stay several days, where they can "camp out," and if they bring food ready cooked to last them during their stay, and a blanket, they can be "at home" at very slight expense.

We worked hard last year to make our exhibit a success, so we did not have to urge the Fair association very much to adopt what we considered a good premium list. I believe, if bee-keepers would do their part, there need be no fears but the different Fair associations would do theirs. Of course, the county Fairs cannot offer such inducements to our specialty as can these district and State Fairs, where thousands are in attendance every day.

I felt like congratulating Prof. Cook and his co-laborers over their success in getting the Michigan State Agricultural Society to adopt such a good premium list as was published in the BEE JOURNAL of January 24th last, and I am sure they will not feel hurt and give us "the cold shoulder" because we have "succeeded beyond our most sanguine expectations." It is all for the "common good."

A new feature that we have introduced is the offering of a premium for comb foundation machine, making best foundation on the grounds. I have invited Mrs. Dunham, Messrs. D. S. Given & Co., J. Vandervort and W. C. Pelham to be here with their foundation machines, and all have promised to be here, if possible. A. I. Root has also been invited and promises to be here if possible, but is not sure that he can bring a mill. I have also asked C. Olm to be here with one of his mills, but it is not time to hear from him yet. The prospects now are for a fine display, and a pleasant time among the bee-keepers.

Messrs. T. G. Newman, C. F. Muth, and James Heddon have promised to be here, and the Hon. I. N. Cotton, President of the Indiana State Bee-Keepers' Association, will represent Indiana on the awarding committee. Dr. Besse, President Ohio Bee-Keepers' Association, and Mr. Dougherty, Secretary, Indiana Bee-Keepers' Association, will "try to be" here.

I will gladly answer all inquiries in regard to our department, and send a premium list, with rules and regulations and entry blanks, as soon as printed, to all applicants. They need not "enclose stamp for reply," but should write name and address plainly.

Wagon Works, O.

Simpson Honey Plant—Figwort.

T. ELLICOTT.

A great deal of bloom can be obtained from it the first year, by starting the plants early in the spring, in a greenhouse or hot-bed. A great many plants can be grown in a small space. I had some started in a greenhouse, last spring, and found that a thousand plants could be grown in a box 20 inches square, until large enough to transplant. It grows rapidly; some of my plants were over 6 feet high, the first season, and had a great many branches, from 2 to 3 feet long. I counted over 2,000 seed balls on a plant.

I set the plants, 2 feet apart each way, and think they require that much room, to do well. I sowed some seed in the fall and some early in the spring, in the garden, but none of the plants grew more than 2 feet high, and only had a few blossoms on them.

I believe, from the length of time bees remain on each blossom, and their eagerness to work on them, that it is a splendid honey plant. The

Simpson Honey Plant.

shape of the blossom and its natural position on its stem, is such that it cannot be penetrated by rain, consequently the nectar cannot be diluted or washed out, and bees will work on them almost immediately after rain. They work on them all day long, when the weather is such that they can work, which indicates a continued flow of nectar, and I think adds a great deal to the value of the plant. It is easy to transplant, but requires a good deal of moisture to make the seed grow. I have no seed or plants to sell.

Fentonville, Mich.

[This plant, figwort (*Scrophularia nodosa*), is often called carpenter's square, because it has a square stalk. It is also known as rattle weed, as the seeds will rattle in the pod; heal-all, etc. It blooms from the middle of July till frost. Mr. J. A. Simpson, Alexis, Ill., first called attention to it as an excellent honey producer, and that gave it the name of "Simpson honey plant."—ED.]

For the American Bee Journal.

Developing a Home Market.

A. J. HATFIELD.

Myself and son, having, at the close of the honey season of 1882, about 6,000 lbs. of honey to dispose of (4,800 lbs. being extracted), which would net us from 7 cents to 9 cents, as reported in Chicago, thinking we could do better by selling our own honey at home than to ship it, we determined to make an effort to do so, but later changed our plans somewhat, in that we arranged with several of the grocers of South Bend and New Carlisle to sell for us on commission, and in doing which have saved a nice profit above selling at wholesale.

To carry out our plans, we first ordered several hundred tin cans and pails, ranging in size from 1½ to 2½ and 5 lbs., and after neatly labeling, we filled them with No. 1 extracted honey, preparatory to attending our county fair, to be held at South Bend.

Assisted by a good brother apiarist, we made an exhibit of comb and extracted honey, bee-hives, extractors, etc., that gave general satisfaction, as well as to put in five days of hard work.

We had hoped to have the privilege of selling honey at the fair, but could not do so, until the last afternoon, but our display and the few sales we were able to make, assisted in making many sales afterwards. We next proceeded to canvass the town, selling samples, which we had been disappointed, to a great extent, in doing at the fair.

Our friend above referred to, selling his comb honey, while our sales were almost exclusively extracted (our comb honey being sold by the crate, or left on commission with our grocers), and as sales were made, families were directed to our grocer where more honey could be had, and at same prices, when wanted.

When putting up honey in pails, full weight was given, and, in selling, the wholesale price of the pails was added to that of the honey. We also made arrangements with our grocers to pay the same prices for them if returned in good condition. This arrangement added materially to our sales, although but few were returned, still they expected to return them, at the time the sale was made. This, of course, could not be done in a distant market very well.

After selling up to Feb. 1, and supplying our grocers with what they might be able to sell, the remainder of the season, we still had some hundreds of pounds on hand. We concluded to try what could be done selling to the farmers in our vicinity, and our success has been very gratifying.

When extracting we stored the honey in stone jars, mostly 2 gallon jars; these we have been selling to the farmers at a little less price per pound than we sell in pails, it being something of a wholesale trade, and saved the trouble of liquefying the honey, to get it into pails.

At this time we have but little honey on hand, and I am satisfied we

have laid the foundation for good sales in the future, and have introduced the use of honey into very many families that had not previously used it, and others, that had used it sparingly, have been using it quite largely, this winter.

Our experience has demonstrated that a pretty general effort in this direction would add very largely to the consumption of honey, and we should not read of overstocked markets, as at present. My friend, above referred to, in his canvass, probably sold some 200 lbs. of comb honey.

New Carlisle, Ind., March 7, 1883.

[This is the way to create a market, and lays the foundation for a large and increasing trade in honey every year. By getting a few hundreds of "Honey as Food and Medicine," and having the producer's name and address on the first page, will greatly add to the efficiency of the plans. Were bee-keepers to follow this plan of creating a market, we should hear no more of overstocking the markets with honey, and we should not only be blessing our fellow-beings by giving them a pure sweet, but be obtaining a much larger profit for the labor and care of the bees during the season. Let all try it.—ED.]

For the American Bee Journal.

Clamp Wintering and Ventilation.

WM. BRADFORD.

In November last, I visited a neighborhood in Ontario, where the keeping of a few bees was quite common among the farmers. The modern system of bee-keeping, with its accompanying bee books and journals, had not penetrated the locality, and to have talked of brood frames and sections or foundation, queen-rearing and extracting, would have been like speaking in an unknown tongue, but burying bees for winter was quite a common practice, and, in one case, I saw the manner of doing the work.

The usual plan is, to dig a trench about a foot deep, and a little wider than the hives. Where I saw the work done, the soil was gravelly hardpan, and a pick was used to make the excavation. In the bottom of this trench, a couple of rails or poles, about 6 inches in diameter, are laid, with some 6 or 8 inches of space between them. The hives I saw, in use, were common box hives; some of them very large. The season, I was told, had been a very poor one for honey, and no boxes had been used on top for surplus, and it may be inferred that they were sealed tight at the top, and that there was no upward ventilation. They were placed on the poles as close together as they would stand, and without bottom boards. Straw is then packed on all sides and the top of the hives, and the whole covered with dirt. Provision is made for drainage, but none for ventilation.

My informant did not fear the attack of mice. He thought a mouse would have a hard time of it if he meddled with a hive. I was assured that the loss of bees, wintered in this way, was trifling, and that the consumption of honey was very small. The party referred to above, thought that 5 pounds would winter a colony.

The question of winter ventilation seems to be receiving a large amount of attention from correspondents. The views of Mr. C. J. Robinson, as to clamp wintering and ventilation, have gone the rounds of the bee papers, and I note with some surprise, the ardor with which his theories have been attacked by various writers. I assume that in saying, that in his clamps there was a partial vacuum, he means partial absence of oxygen, and not of all air or gas; and looking at what, I think, was the meaning of the writer, rather than at what he says, it appears to me that, possibly, profitable inquiry may be made in this direction. I do not know what the power of a bank of earth is to absorb carbonic acid, and to furnish oxygen in its place, and I have no authority to which I can refer in the matter, but I should not like to be shut up for many minutes in such a clamp as I have described above, after November rains had saturated the surface soil and frost had congealed and sealed it tight. I do not think that the air can long remain, such as an animal, requiring a full proportion of oxygen, could breathe with impunity.

It is apparent that in the matter of the proportion of oxygen and carbonic acid in the air they use, that the requirements of bees are different from those of most larger animals. Give a colony of bees a box, with from 1 to 2 cubic feet of space in it, and a round hole an inch in diameter for entrance, and they will seal up every other aperture air-tight. Then, with the circulation of air within impeded by the compartments into which the space is divided by the combs, and with these compartments filled with the living insects, they cannot only exist in a quiescent state, but they work, eat and breathe, and rear their young. The queen, with the tremendous strain upon her vital powers, involved in the performance of her functions, never seeks the stimulus of the purer outside air, but works contentedly in the midst of her clustering subjects, as do her progeny for days after they emerge from the combs. The growing young, in their cells, sealed and unsealed, are still farther excluded from the pure air, which we are disposed to think is as necessary to them as to us. The inference is plain, that they work without detriment, in an atmosphere highly charged with carbonic acid. That they can winter in an atmosphere similarly impure, needs no proof. The questions for inquiry are, how large a proportion of oxygen is necessary to their safety, and what influence, if any, has a large proportion of carbonic acid in reducing their activity, and the consumption of honey and conserving their vital forces. That there is proof that it

does or can do this, I do not claim, but only that the negative is not established, and that it is not so improbable as to be dismissed without consideration. Bees, we have all seen reduced to a quiescent state by cold, and revive again without apparent injury. Frogs, and some other cold-blooded animals, in their winter quarters, furnish us examples of a torpid condition, with very trifling consumption of oxygen for long periods of time.

This subject, of upward ventilation, is a question of the safe disposal of the watery vapor expired by the bees, not of the carbonic acid. If all were known that can be known about the proper adjustment of a current of air through the hive for this purpose, it would still be a difficult matter to regulate properly in every case, with the varying strength of colonies, and would change outside temperature, and require great care, experience and skill. If a safe way of wintering can be secured, better approximating the natural method, by dispensing with this upward current, it would be worth searching for.

St. Lawrence, N. Y.

For the American Bee Journal.

Best Way to Market Comb Honey.

MRS. L. HARRISON.

Mr. E. B. Southwick expresses my feelings exactly, with reference to the one-pound section. Before this insignificant package was put upon the market, honey changed hands faster than it does now, and at a better price per pound, a five-pound package sold as readily.

I do not know what suits Eastern people, for I never interviewed them on the subject, but Western people, with their expansive views and capacious stomachs, desire a good square meal. A one-pound section is beneath their notice; cannot see it; their optics are too large to take it in. When they used to order their supplies, a box of honey included, it amounted to something; it could be cut out as needed, but they would be afraid that those little mites of honey would get lost—the children would carry them off to their play house.

I interviewed the dealers when they were selling the prize box, in this shape, a number of them were fastened together with little wooden strips, forming a long box, and the ends glassed. The reply was, "We do not want it in any better shape than that; it is good enough; a customer can take a whole box, or part, just as he likes."

We have always sold our honey in this shape, mostly to families, with this exception, our boxes are larger, seven of them weighing about 15 pounds. Consumers can take out the glass and cut out the honey as needed, and the remainder is safe from dust and insects.

I saw a shallow box of one-pounds, in a grocery, this week; it was uncovered, and some one had run against it, knocking the tiny things over, break-

ing them badly. If producers persist in putting pounds upon the market, they had better nail two of them together, then a consumer would be ashamed to ask a dealer to take off one.

Peoria, Ill.

Northeastern, N. Y., Convention.

The thirteenth annual convention of the Northeastern Bee-Keepers' Association was held in Syracuse, N. Y., Jan. 9-11, 1883.

After the regular routine of business, the topic, "Different races of bees," was introduced and discussed by Mr. Jones, his choice being the Holy Land bees. They are not so cross as the Cyprians, and they are better breeders than the Italian. He has had too few pure Cyprians to breed from to make a fair test of them. The Holy Land bees winter better, and are in every way superior to Blacks or Italians. They also gather honey earlier. The pure Holy Land bees, or cross between them and the Italian, using a Holy Land queen, produce one-third to one-half more honey than the pure Italian. Some may think the Holy Lands are too cross to handle, but they show the same determination to gather honey that they do to protect their stores. They are scarcely as large as the Italian bee, are quicker in their movements, and their hair is greyer; their color is lighter also than the Cyprian, and their rings are more of a lemon hue. All pure Holy Land bees were brought from Mount Lebanon and the Valley of Sharon. The Cyprians were nothing more than Holy Lands, brought about by being isolated. Italians came from Holy Lands originally.

Mr. Hoffman described a variety he imported from Germany, called the Caucasian. The docility of these bees is remarkable. Their comb and honey are far whiter than ordinary, and winter as well as any. They are rather dark, have silver-grey hair and narrow yellow stripes, and are not as thin and pointed as the Cyprian bee.

Mr. Jones, in answer to a question, stated that Holy Lands will not run off the combs like black bees. They will fill their cells full of honey, and are swifter and make longer journeys than any others. They will fly in 13 minutes the same distance that it takes the Italians to traverse in 17 and Cyprians 14 minutes.

Mr. Doolittle said he wanted to live in peace with his friends and bees, but found it impossible to keep on good terms with the Cyprians. He thought the Holy Lands as easy to handle when they had a queen as the Italians, but did not want any more Cyprians; his Holy Land bees made whiter honey than his Italians. Thought them detrimental, in breeding out of season.

Mr. Vandervort said the foreign races were too cross, and he got rid of what he had.

Mr. Houck said, the most he knew about the foreign bees was from reports received, had but very few reports favorable to Cyprians, and some

good reports from the Holy Lands. Found the Holy Land bees nearly as gentle as the Italians.

Mr. Jones said he never saw any bees that could rob the Holy Lands; found they were no worse to rob others than other bees. Thought the Holy Land bees quite as hardy as the Italian or black bees. He said that queens reared in small nuclei did not give as good satisfaction as those reared in large colonies. He thought the time would come when a cent's worth of chloroform would serve for introducing a queen in any hive and at any time of the year.

Mr. Peet had seen queens introduced by first dropping them into honey and then putting them into the hive, and that the success of the method had given good satisfaction, as a queen was seldom lost by this process.

Mr. Jones explained his chloroform process as follows: Put one-half teaspoonful of chloroform on a sponge, place in a smoker, puff a little of the smoke into the entrance of the hive, and then drop the queen into the hive. He never lost a queen by this method.

The question of using half-pound boxes was warmly discussed, and a resolution was passed, "That it is the unanimous opinion of the Association that half-pound sections are not practicable or profitable to the producer at anything less than 40 cents a pound."

The topic of "Marketing our products," was taken up for discussion.

Mr. J. M. McCaul, of New York, addressed the convention. He wanted to interest every bee-keeper in the matter of awarding prizes, with the view of getting the producer to improve on the grading of his honey. He thought the paper boxes, used by Mr. Schotfield, a great improvement, and the very best manner of putting up the one-pound packages of comb honey. The two-pound boxes should invariably be glassed and crated, 12 to a crate. The one-pound packages should be put up 24 to the crate. His opinion of the half-pound boxes was decidedly unfavorable to them. He did not want the trade to become so contracted as that, and advised bee-keepers not to use them, under any circumstances. Upon the whole, he thought the 5½x5 inch box the best for the bee-keeper to use. Extracted honey for the New York market should be put up in firkins or small barrels, weighing from 150 to 175 pounds. They had no trade for extracted honey put up in small pails, but had a trade for glass bottles and jars. He would advise bee-keepers to put up their extracted honey, for home consumption, in small packages or pails.

Mr. Jones thought the best manner for putting up honey for the home trade and to increase the consumption of extracted honey, was to put it up in small packages. We must educate the people to use our honey in preference to the adulterated sweets, found on the market to-day.

Mr. Root thought that the Western bee-keepers had greatly injured our markets by putting their comb honey on the market without glassing. The Association should pass a resolution

asking Western friends to glass what comb honey they put upon the New York market. He related his experience in selling extracted honey direct to the consumer.

Mr. L. C. Root read an able paper on "Extracting and curing honey," which was listened to attentively. He said that honey from Pompeii, 3,000 years old, was now in the British Museum, and is in a perfect state of preservation.

Mr. Jones said, there was not a doctor living who could produce a better remedy for colds and hoarseness than honey. An eminent Roman priest had found that Jamaica rum and honey mixed and taken in doses of one teaspoonful, taken very often, would cure the worst cold, coughs and consumption in its worst stages, which baffled our best physicians. Mr. Jones also gave the following recipe for preparing any kind of pail or bucket, no matter how musty, or of what material made of, so that it would keep honey perfectly: Take pure hot paraffine and coat the inside of the vessel. It would more than pay for all the trouble and expense. The cost was very little.

Aside from the formal proceedings common in all deliberative bodies—and short remarks from many different individuals, commenting on the essays read—the above contains about all the proceedings of interest to our readers, so far as we have received them. When the essays come to hand we shall classify them and publish through the year such as are best adapted to the immediate wants of our readers, and thus endeavor to give them "meat in due season."—*Bee and Poultry Magazine*.

Convention Notices.

The Southeastern Michigan Bee-Keepers' Association will hold their next meeting at Adrian, Mich., April 18, 1883. All are invited. Reduced rates at hotel.

H. D. CUTTING, Pres.
Clinton, Mich.

H. C. MARKHAM, Sec.
Ann Arbor, Mich.

The semi-annual meeting of the Western Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to bee-keepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, Sec.
Kansas City, Mo.
J. A. NELSON, Pres. Wyandotte, Kas.

The spring meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, Sec.

Quite a number of the leading bee-keepers of Missouri and Kansas met at the Court House, in Independence, Mo., December 23, 1882, and organized a bee-keepers' convention, which was named the "Western Bee-Keepers' Association," by electing the following officers for the ensuing year: Jas. A. Nelson, of Wyandotte, Kans., President; L. W. Baldwin, of Independence, Mo., Vice-President; S. W. Salisbury, Kansas City, Mo., Treasurer. The Association passed a resolution to invite all bee-keepers within a convenient distance, to meet with us at our next meeting and lend us their councils. Adjourned, to meet again at Independence, on the last Saturday in April next, at 10 o'clock, a. m. J. D. Meador, P. Baldwin, C. M. Crandall, Committee.

The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address; Essays: Prof. A. J. Cook, on Wintering Bees; S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. WOOD, Sec.
North Lansing, Mich.

The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, Sec.
Coopersville, Mich.

The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.
Kingston, Texas.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.
Christiansburg, Ky.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

SELECTIONS FROM OUR LETTER BOX

Moldy Combs.

I have some combs badly mildewed, can you tell me how to get them in good condition again? A party, who has kept bees for 6 years in Colorado, told me that he took off 7 tons of honey from 150 colonies, and that the average is 200 lbs. per colony.

PHIL. REARDEN.

Jamestown, Colo., March 17, 1883.

[The bees will clean up the moldy combs, if given them one at a time, in spring.—Ed.]

Bees Confined 130 Days.

The bees have been confined since Nov. 13. I put 23 colonies in the cellar, and left 7 out, 3 of them were floated some distance by water being dammed up, in the snow, about the first of February. I expect some loss from those that have had no flight yet; the thermometer is down to zero every morning, and we have snow drifts from 3 to 15 feet deep. Those in the cellar seem to be all right, yet some are getting a little uneasy. 130 days without a flight, who can beat that?

PERRY MCKAY.

Spofford, N. Y., March 23, 1883.

Matrimony Vine, Etc.

Last season was a pretty good season for our "pets;" crops of all kinds have yielded well; but just how well bees could have done, cannot be said, from the fact that there are no practical bee-keepers, to my knowledge, in this section of country, the bees being kept by farmers, in box hives or the cottage bee-hive, a patented concern, worse than a box hive. I have 2 colonies, one good and strong, the other rather weak from the effects from dysentery. I put my bees in the cellar, Dec. 1, 1882. One colony became very uneasy the beginning of February; every few days a large quantity of dead bees accumulated on the bottom board; the hive became very damp. I bored a hole in the top of the hive, and they became more quiet (after boring the hole, I laid a bunch of wool on the top, to keep the bees in), with fewer dead bees, till Feb. 15, when we had a pleasant day, but much snow was on the ground. I brought the affected colony up, let them fly out, and returned them to the cellar; this cured them; there were no more dead bees nor dysentery, but the colony is weak from disease, and bees perished on the snow, the day I let them fly. The bees are the common black bees, which I captured in the woods last August. I found 4 bee-trees; the bees I united into 2 colonies, let them build comb, then bought "wild honey" and fed them up for winter quarters. I now have them on their summer stands, doing well. The elms are yielding pollen at present. I think I will make a practical apiarist, for I "fill the

bill" exactly, as given by Dr. C. C. Miller, in February number of the BEE JOURNAL. Yes, I not only lay awake at night; talk about bees so much, that my wife and children also talk about bees in their sleep, and take as much delight in the honey-bee as I do. When the proper time arrives, I shall transfer them to some movable frame hive. In the meantime I will content myself with reading the BEE JOURNAL and the A B C in Bee-Culture, etc., and build up an apiary as fast as my means and experience will admit. Please give a description of the matrimony vine, as spoken of by Wm. Stolley, of Nebraska, in the BEE JOURNAL, and give its botanical name.

Fulton, Mo. D. R. PHILLIPS.

[The matrimony vine, *Lythium barbarum* belongs to the order *Solanaceae*, which includes the potato, tomato, night shade, horse nettle, ground cherry, bitter sweet, egg plant, etc. It is easily propagated by layering.—Ed.]

A Long Winter, but Bees All Right.

Bees have had a long winter, but mine are all right yet, and I think it is the same in this vicinity generally.

L. M. ROBERTS.

Fort Atkinson, Wis., March 28, 1883.

Used 80 Bushels of Chaff.

I have kept bees for 30 years, and once thought I knew all about them, but have since found that I knew but little. Wintering bees baffles me yet. I think Mr. Heddon is right in his pollen theory. If one tries all the plans of wintering, he will have no time for anything else. I have used 80 bushels of chaff this winter, and have bees prepared in five different ways; some are in the cellar, some in cold frames, some with pollen and some without it. One colony, having no honey, I fed till Feb. 10, when the bees all died, as it was too cold to feed, 10 degrees below zero.

Nineveh, Ind. W. D. SMYER.

All Hopeful—Bees have Wintered Well.

Bees have generally wintered well, and we are all hopeful, but can hardly expect another such honey season as the last.

J. L. WOLCOTT.

Bloomington, Ill., March 27, 1883.

Lady's Report for Two Years.

The terrible winter of 1880 made sad havoc with bees here, as elsewhere, and of the 47 fine, strong colonies, so carefully packed in the fall, June 1, 1881, found us with bees in but 9 hives, and of these, only 5 colonies were thrifty. We equalized bees and brood, and felt we had but a poor start for the season. Were not discouraged, though things went somewhat askew. I did my work alone for a family of 7 to 9, till the middle of September. Mr. Parsons was seriously ill the entire month of October, and a part of November, and Nov. 1, the "champion queen" of the county, our "daughter Mabel," took up her abode

in our home. "Blessed bees" failed to receive all the attention they could have endured that summer, but our expenses were only 75 cents, and recompense 278 $\frac{1}{4}$ lbs. of salable comb honey, and 175 lbs. of extracted honey; the wax I had to let go. We obtained 20 cents per lb. for comb honey, and 15 cents for extracted honey. Some of the 1880 crop also brought 20 cents, thereby bringing the average price of that year's crop to 18 cents per lb. I packed the bees, which had increased to 13 colonies, on the summer stands, in building paper and boards; they were left in summer hives, with sections at sides and above them. (We were too ill to do more for them.) They came through the winter, 9 colonies being strong and thrifty. Our expenses, this year, were \$6.25, and recompense 1,113 $\frac{1}{2}$ lbs. of salable comb honey, 35 $\frac{1}{2}$ lbs. of extracted honey, and 10 lbs. of beeswax. The stock increased, by natural swarming, to 23 colonies. They are on summer stands; some in summer hives with straw in ends of hives and covers; some in winter hives with division-board at each side of the frames, and straw in the covers. All are encased in building paper and boards, and are well banked at the front and back; have good board roof with tar paper roof over it, lapped well over the edge of the roof boards at each side; have 35 lbs. and upwards of early made, well-capped honey, and we hope for the best. All are now quiet, and I find no indication of frost at the entrances of the hives. We have had steady, cold weather and good sleighing since Thanksgiving day; the mercury having fallen as low as 16° below zero; that is the extreme.

MRS. MYRA L. PARSONS.

Linwood, Mich., Feb. 6, 1883.

Red Clover, Italian Bees, Etc.

In the report of the Maine convention, in the BEE JOURNAL of March 7, page 123, I am made to say that I "had often observed black bees on red clover, but no Italians." It was not me, but another man who said that. I have been looking, during the last three summers, to find bees gathering honey from red clover; having partially Italianized my black bees, with that end in view, there being lots of red clover about here, with piles of honey, as well as money, in it; yet, never have seen the first honey bee, either black or Italian, gathering honey from red clover. I have seen them buzzing around and over it, but when they settle, they invariably alight on white or alsike clover, or some flowers beside red clover.

Were I to offer 50 cents ahead for all the honey bees found gathering honey from red clover about my locality, I do not think I shall be called on for the first 50 cents.

So far as my experience goes with Italians, they are poor comb builders, that is, they make it uneven. My Italians produced dark comb and dark honey; at the same time, the blacks were producing white comb and white honey, that sold from 2 to 3 cents per lb. more in market than that put up by the Italians.

I think the quantity stored by my Italians about equal to that stored by my best blacks, but my hybrids stored more than either. The quality of that put up by the hybrids, seems to be a mixture of the two.

I think the Italians are a little more prolific, and more liable to dwindle, but, when putting up white comb honey for the market, the black bees carry off the palm with me. Whether the Italians do better in their own native hills, I cannot say. There should be some great exhibition, where all can compare combs, and see for themselves. I think if Maine men would take more pains to improve their own bees, they might make a great saving in time and money.

JOHN REYNOLDS.

Clinton, Maine, March 21, 1883.

Rainfall in California.

Quite a mistake appears in the Weekly BEE JOURNAL of Feb. 28, under the heading of "Scarcity of Water in California." On Feb. 5, I reported the rainfall, so far this winter, $2\frac{1}{2}$ inches; but in the BEE JOURNAL it reads $22\frac{1}{2}$ inches. If we had that much rain, we would not now be complaining of drouth. Since my communication of Feb. 5, we have had $3\frac{1}{2}$ inches more of rain, making 6 inches for this season. There is little probability of getting much more rain this season, consequently the outlook for surplus honey is not encouraging, although the bees are now doing well, working on the *Alfilerio* (pin grass) and sycamore. I have noticed that everything that has bloomed, up to date, is very rich in nectar. What the future will bring, is yet unknown.

J. E. PLEASANTS.

Carbondale, Cal., March 19, 1883.

[True; that was quite a mistake, and we wonder that it was not discovered. We try to avoid mistakes, but perfection does not yet exist in mortals.—ED.]

Lost 2 Out of 83 Colonies.

The spring here is cold and backward; bees are not in very good condition, generally, as far as heard from. Some have about one-fifth left; nine are in good condition yet; I lost 2 out of 83; but we are not out of the woods yet. A. D. BENNETT.

Janesville, Iowa, March 26, 1883.

Beginner's Satisfaction.

I commenced in the spring of 1882, with 2 colonies, and increased to 9. I bought a few at \$3.35 per colony, in box hives, which I will transfer to movable frame hives. I formerly lived near Mr. Hill, of Kendallville, Ind.

Edna, Kans. W. E. POTTS.

No More Loss than Last Winter.

Bees are wintering fairly here, notwithstanding the severe winter, and I do not think the per cent. of losses will exceed that of last winter, unless very unfavorable weather should intervene between this and warm weather. I have about 20 colonies

packed on their summer stands, while the balance are stowed away in the cellar, to remain until the weather becomes warm enough to justify their removal.

CHAS. S. BURT.

Brecksville, O., March 26, 1883.

Moving Bees.

I have 2 colonies of bees, in the cellar. I wish to move them 10 miles on the 11th of May. I cannot move before. Will it injure them, or be the cause of many being lost? It is where I kept them last season. Please give best plan of setting them in wagon, and of preparing for the journey.

Port Elgin, Ont. BEGINNER.

[By that time it should be warm enough to move them with safety. Put them in a spring wagon, with frames running across the body of the wagon. For manner of preparing them, see directions given on page 77 of the BEE JOURNAL for Feb. 7, 1883.—ED.]

Stimulative Feeding.

The question is often asked, about this time of the year, how shall we keep our bees quiet in the cellar, and yet have them breed up until we want to put them out? We will suppose that your bees were put into a warm cellar last fall, and are in a healthy condition, and that each colony has plenty of stores. Now place near the entrance, or at any place where the bees can get at it, and it will not leak or run into the hives, a piece of ice, and, as often as it melts, replace it; the longer it is used, the more they will require. I prefer ice to water, as water takes up the poison that is in the atmosphere, and the ice will keep the air more humid; in this way I have increased ordinary colonies twofold by the time they were set out on the summer stands. Do not give ice more than 4 or 6 weeks before putting them out in the spring. Then take a frame of honey and place it in the center of the brood-nest (if the colony is strong enough to move the honey out of the comb and not chill the brood); make the hive as warm as possible, and, if the weather is cold, close the entrance to quite a small one. As soon as sufficient bees are hatched, which will be according to the strength of the colony, place another in the center, and so continue until flowers secrete honey, so that the bees can get plenty to use each day (if you have no honey in frames, put the feed in the empty frame by pouring it from a distance above, in a small stream), then place in the center, the same as a frame of honey; as the bees move the honey or feed from the comb, the queen is sure to fill it with eggs, and the bees will feed the young. When honey comes plentifully from the flowers, place empty frames of comb in the center of the brood-nest. If, at any time, for any reason, honey should cease, and there is none in the center of the hives, immediately place combs, filled with honey or feed in the center of the brood-nest. If these rules are ob-

served, bees will continue to rear brood until the main honey crop comes, when you will have to see that the bees do not crowd the brood-nest with honey. Colonies that are too weak to work thus, should be fed, using some kind of a feeder that will not let out any of the original heat. No matter how much honey the colony has, if it is weak, feed it. I cut a hole through the quilt, over the cluster of bees, and place the food in a feeder, made thus: Make a tin cup, 2 inches deep and $2\frac{1}{2}$ inches in diameter, without top or bottom, and another that will just squeeze into it, without top or bottom (the inside cup should be 3 or 4 inches deep); place the cotton cloth over the largest cup, squeeze the other into it, until it comes within $\frac{1}{2}$ inch of the bottom; now you have a cup without top or bottom, with a partition $\frac{1}{2}$ inch above the bottom. Wet the under side of the cloth with the food, so as to attract the bees; set it over the hole in the quilt, put in the food, quite warm, at a certain hour each day, and feed just what they will use. I have used the above feeder for 15 years, with the best of success.

W. H. B.

Oran, N. Y., March 27, 1883.

Bee-Keeping in Minnesota.

We have been having a cold, long winter, 41° below zero was the lowest, and 42° above zero was the warmest, up to March 14, and still we are having cold spells. The thermometer, this morning at 6 a. m., showed 12° below zero. I set out 130 colonies of bees on the 14th inst., which I wintered in a double-walled bee-house, but the weather was hardly warm enough for bees to take a fly (which they needed badly); a large number of them dropped on the snow and could not rise again. It was 43° in the shade, and 60° on the south side of buildings, in the sun, above zero. Cold winds have been prevailing for the past three days, with from 2 to $2\frac{1}{2}$ feet of snow in the woods, and north side of hills, which is hard enough to walk over anywhere. There were about $2\frac{1}{2}$ bushels of dead bees on the floor of the bee-house, though, with the exception of a few colonies, they are in splendid condition; most of them have consumed but little honey, and the combs look nice and clean; also there are plenty of bees. My 30 colonies, which I wintered out of doors, came all through safely; they were packed with chaff, on the south side of the building; and were covered with $1\frac{1}{2}$ feet of snow for over 2 months; then the snow melted between the hives and the top of the snow; as it was too warm and damp for the bees, I cleared it away; the coldest weather was over, too. I have no cushions on top or anywhere, and left the entrances, on all my hives, open the whole width, but made holes through the combs, last fall, for passages. Nearly all bees in this vicinity, as far as I have heard, are dead; their keepers gave them no protection. I have not lost any out of 160 colonies, so far, this winter. I believe a ball of snow on each entry, in portico, is a good idea, as Mrs. A. B. Winder (on

page 139) has stated. Where bees are kept in a temperature from 40° to 45°, through the winter, they seem to get dry, and are in need of water, towards spring. Mine have been kept on the above temperature, and, although, in a healthy state, they have been very uneasy for the past month, and a great many came out, probably in search of water, and dropped on the floor. I could not think of such a convenient and practical way to water my bees, like Mrs. Winder, and when the BEE JOURNAL, with its precious contents, came to hand, it was too late for my bees, as I had them out, already. H. M. Morris, on page 145, refers to my experience. Here, corn does not yield honey every season; at least, not enough to notice. I have only experienced 2 seasons in 8, that my bees gathered large quantities of honey on corn. Some years I could hardly see a bee visiting the corn, while in bloom, with large fields close by the apiary. Corn honey is the very finest and best that my bees gather.

C. THEILMANN.

Theilmanton, Minn., March 19, 1883.

Fruit Trees Killed by the Frost.

I have now set a part of my bees on their summer stands. I lost 3 out of 60. I am now satisfied that they will winter in this cold country, packed in sawdust, without freezing. The past winter has been the coldest one on record in Iowa. Many apple trees froze so hard that it will kill them. I had 150 trees that had been bearing; all were killed but 5. Where trees are planted on high ridges, probably only about one-fourth are dead.

H. C. CLARK.

Palmyra, Iowa, March 26, 1883.

Tight Top Bars of Frames.

I wish to say through the BEE JOURNAL that I have been using the American hive, improved to suit my own notions, and I find it very convenient; and the alteration is in cutting the hive down to 15 inches in length, also varying the pitch of the bottom board, shortening the frames and making them 11 $\frac{3}{4}$ x11 $\frac{1}{2}$ in the clear. The top bars of the frames fill the hive, over the top, leaving 3 inches closed at each end of the frame, then cutting 3 inches, $\frac{3}{8}$ of an inch in width, at each side of hive, leaving 2 inches closed in the centre; then the quilt is placed on top, pressed down with a thin board, till the time of putting on my racks, which hold 12 two-pound sections. And as this rack of sections is filled, I raise it up and put another under, and as long as there is a flow of nectar, the bees keep filling them; here is one advantage of the closed frames, concentrating the heat and throwing it immediately into the surplus box, where you cannot get too much, as long as it arises from the bees; the next advantage is in economizing the labor of the bees, in regard to gathering propolis, where they could as well be gathering honey, and would be, if you had frames with closed top bars for 3 inches at each end. I have never handled open or narrow top frames till within the last

two years; in this length of time I have handled quite a number, for my neighbors, and in those I have opened. I find more propolis in one hive than in ten of mine, that have closed frames. I believe if the labor of the propolis-gathering was spent in honey-gathering, it would make from 5 to 10 pounds of honey to each strong colony, which would be of some account, while the propolis is of no account to you or to the bees, while packed between the frames. R. CORBETT.

Manhattan, Kans.

American Hive, Honey Vinegar, Etc.

Please give the proper dimensions of the American hive and frame, as I find there are several sizes in use in this vicinity. Also please give the dimensions of frame to fit extractors marked for 13x13 inches. My frames are 12 $\frac{1}{2}$ x11 inches, with 14 inch top bar, with cross bar in the middle, consequently are built down to from 12 to 13 inches, and I find the long ones are set on the bottom of the basket, and slip about at the top, and occasionally the top bar strikes the can.

In the BEE JOURNAL, page 143, Mr. W. Z. Hutchinson gives us Mr. Bingham's plan for making honey vinegar, which he says was good. We made some last fall from the washings of vessels, after extracting. The honey was first-class, smartweed honey, but the vinegar had a sickening taste about it, and the only way we could use it was to mix it with sorghum vinegar, the kind we were using. Does honey vinegar usually have such a taste? JOSEPH BEATH.

Corning, Iowa.

[The American frame should be 12x12 inches, but that hive has had so many changes, and been varied by so many that use it, that it would be difficult now to determine a standard size for it. Mr. King does not give any size for it in his new Text Book.

As your frames are 12 $\frac{1}{2}$ with a 14 inch top bar, an extractor, with comb basket 13x13 inches, is just the thing; the ends of the top bar will rest on the top of the comb basket.

We never heard of honey vinegar having a sickening taste, though we have used considerable of it.—Ed.]

Queens Reared in the South.

On page 141, G. M. Doolittle writes that he has a colony of bees to which he gave a Texas queen last June, that they were the first to show signs of dysentery, that they were nearly all dead, and what remained were in a deplorable condition. As I have been thinking of sending to Texas for queens, this spring, I would like to ask Mr. Doolittle if he thinks bees, from a queen reared in the South, are as hardy and well able to stand the long, cold winters of the North, as those from a queen reared here? It seems to me they are not, but I may be wrong. I merely ask for information. It is true we can get queens earlier and cheaper, but will it be ad-

visable to send there for them? I would like to hear from any others who have had experience with Southern queens.

T. S. JOHNSON.

Bogart, O.

Hints About Rearing Drones, Etc.

Professors Siebold and Leuckhart were right; drone and worker eggs are not alike, yet they are all fertilized by the male bee. The queen has nothing to do in fertilizing her own eggs, when laying. A queen is like all other winged insects; not like frogs and fish. The drone does not accompany the queen when she is laying. When they want drones, the whole colony engage in the work; the same in rearing queens. Bees make drones and queens, when they want them; it is the workers that regulate the laying, not the queen alone. Bees never eat nor remove eggs from one cell to another; they can destroy eggs when they desire, but never eat them. Bee-men should be careful about importing new kinds of bees, and not let the drones fly, until proved to be better than any we now have, for they may do a great deal of damage. Cyprian drones fly faster and farther than Italians. I think Italians are better than any I have yet seen, for honey-gathering.

Delhi, N. Y. JOHN McCANDLISH.

Bees Strong and Healthy.

I removed my bees from the cellar, where they have been confined for 135 days, and they had no flight for 10 or 15 days before they were put in the cellar. The bees never wintered better. J. J. HURLBERT, 40.

Lyndon, Ill., March 30, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Transferring Bees, Etc.

Will Mr. Heddon please answer the following questions through the "How and What" department of the BEE JOURNAL: I have 8 colonies of bees in box hives, which I wish to transfer to frame hives, this spring, according to your "Progressive Method" (published in No. 28 of the present volume of the BEE JOURNAL), but I do not understand the method fully. You say: "With smoker, drum box, etc., drive a colony from the 'old gum' into the frame hive, filled with foundation. After 21 days the worker brood is all hatched, and a new queen, just begun to lay, in the 'old gum.'" "Now, I can unite with my first drive."

2. How do you manage to catch the young queen, to keep her from going into the frame hive and raising a row with the queen already there? If I can catch the young queen, I would much prefer this method to the old one. Do colonies, so transferred, have to be fed for a few days?

3. What are the distinguishing

marks of a brown German queen?

4. Can a queen-cell be safely introduced to a colony rendered queenless, and how should it be done?

ROBERT L. FREDERICK.

Riverton, Va., March 26, 1883.

[1. After the bees are above in the drum-box, before you put them with the first drive, shake them down on a flat board or sheet, and while they are running into the box, or a decoy hive fixed for the purpose, look them over, find and pick out the queen and kill her. There is no easier method of finding queens than this.

2. We do our transferring during a honey flow, and have never yet fed the new colony. Were we compelled to do it at other times, we should feed, of course.

3. The brown bee differs from the smaller black bee physically, to the observation, as follows: She is larger every way, lighter-colored, and more hairy or downy, than her smaller black cousins. In qualities, her points of superiority are vastly more marked and numerous. Queens differ from each other in appearance much the same as the workers, though not to as great a degree.

4. About six hours after making the colony queenless, insert the cell, by cutting a V-shaped hole in one of the central combs, in which insert the cell, which is held in place by the V-shaped piece of comb attached to it, if you cut it out properly. I have stuck the butt of cells to a piece of section honey box, and hung them down between the top bars with success, but the first named plan is the safest.—JAMES HEDDON.]

About a Location.

1. Allow me to ask about the right kind of a location to keep bees. Would a prairie place do, say 1 mile from timber, with no running creek or branch in $1\frac{1}{2}$ miles, but weak springs of water nearer, with well on the premises?

2. Do bees require an abundance of water, and do the winds blowing on the prairies, disturb their working or destroy them?

3. Will bees do well with land in cultivation, a mile in each direction?

4. Everything else being desirable, or even sufficient as a location, would 15 miles from market or railroad be too far to succeed well, where one wants to make the business profitable?

Bear in mind this is Texas, with sometimes long, dry summers, and high winds in the spring, especially. Salado, Texas. W. P. HANCOCK.

[1. Yes; many succeed with far greater disadvantages.

2. Bees use considerable water, but will find plenty in your locality. High

winds are unfavorable, but not enough so, as to prevent success in windy locations.

3. Yes.

4. No; honey is a commodity that possesses much value in small compass, and weight.

Tiering up Sections, Etc.

1. I am a beginner, and would like to know how to put on sections; horizontal or "flat" as quoted in price lists of Bee-Keepers' Supplies? I use 4 lb. boxes, 5x6x2 in cases; 18 sections in 8 frame, or 21 in 10 frame Langstroth hive.

2. What is the best way of using more than one high, or tiering up?

3. Is there more than one method, horizontal and perpendicular; how are the sections held, and how many tiers high?

4. Are wood separators better than tin ones? J. SHORTT.

Oak Centre, Wis.

[1 and 2. I would first advise the use of one-pound sections, in cases similar to the one illustrated on page 639 of the BEE JOURNAL for 1882. The tiering up process is then very simple and practical. There are other methods, but the one referred to is my choice, which is the reason why I now use it; 5x6 sections could be adjusted in the same manner.

4. A majority seem to think they are minorities, and very small ones at that, have so often been found to be correct, that I shall test the matter of tin vs. wood separators thoroughly the coming season.—JAMES HEDDON.]

Shipping Crates.

What is the best size for shipping crates for the large markets?

MERRITT BLANCHARD.

Sherwood, Wis.

[In answering the above question, I shall differ from many. I use, and prefer, a small crate, which holds 12 sections, $4\frac{1}{2} \times 4\frac{1}{2} \times 2$; 14 sections, $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{3}{4}$; 21 sections, $4\frac{1}{2} \times 2\frac{1}{2} \times 13-16 \times 1\frac{3}{4}$; 24 sections, $4\frac{1}{2} \times 2\frac{1}{2} \times 13-16 \times 1\frac{1}{2}$. The last two being half-pound sections, to be used with and without separators, respectively. I have found the advantages of a small crate to be these: The honey is not as liable to be broken in transit; they take in a large proportion of retail trade, and in a wholesale way.—JAMES HEDDON.]

Errata.—On page 156, in my answer to Mr. Seofield's questions, 3d reply, make a full stop at "disease," and thus change the meaning. It is a double reply. In 5th answer, between "for" and "advertising," put the little word *not*, and thus reverse the meaning. Dowagiac, Mich. J. H.

[The errors were in the copy.—ED.]

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, {
Monday, 10 a. m., April 2, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEEWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7 $\frac{1}{2}$ c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12 $\frac{1}{2}$ c. on arrival.

BEEWAX—Comes in slowly and brings 28 $\frac{1}{2}$ to 30c per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The past month has not reduced the stock of comb or extracted honey, the receipts having been larger than the amounts taken for consumption. Prices are weak and irregular, ranging from 10c. to 18c. for white comb in the smaller frames; dark, very little selling, offered at 12 $\frac{1}{2}$ c. to 14c. Extracted, 8c. to 10c., according to color.

BEEWAX—None in the market.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—All stocks of choice honey in this market, either comb or extracted, have been closed out. Present offerings are confined to second and third grades, and are not large. Were there any desirable quantities now here, they would doubtless meet with ready sale.

White comb, 14 $\frac{1}{2}$ c. to 17c.; dark to good, 11 $\frac{1}{2}$ to 13c.; extracted, choice to extra white, 8 $\frac{1}{2}$ to 9 $\frac{1}{2}$ c.; dark and candied, 5 $\frac{1}{2}$ to 7 $\frac{1}{2}$ c.

BEEWAX—We quote 30 $\frac{1}{2}$ to 33c.

STEARNES & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14 $\frac{1}{2}$ to 16c.—some inferior sold at 10c.; strained at 6 $\frac{1}{2}$ to 7c., extracted at 7 $\frac{1}{2}$ to 8 $\frac{1}{2}$ c., lots in small packages more.

BEEWAX—Scarce and wanted at 33 $\frac{1}{2}$ to 34c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18 $\frac{1}{2}$ to 19c.; second grades, 15-16c.; 2-lb. sections a little slow at 17 to 18c. Extracted very dull at 9c. to 10c.

BEEWAX—None in market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: $\frac{1}{2}$ lb. sections at 30c.; 1 lb. sections, 22 $\frac{1}{2}$ to 25c.; 2 lb. sections, 20 $\frac{1}{2}$ to 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEEWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Special Notices.

Attention is called to the advertisement of D. C. Talbot & Co.'s Comb Foundation Fastener, on page 184.—*1dv.*

I desire to say to those who have ordered my book, that we are now sending out 50 copies each day, and will continue to do so until every order is filled. H. ALLEY.

Wenham, Mass., March 30, 1883.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$5 per 100.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quimby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Bees for Sale!

200 or 300 colonies of Italian bees, in Langstroth hives, in good condition. Price: Single colony, \$6.50; ten or more, \$6.00 per colony. Hybrids, 50 cents less. I will guarantee safe arrival.

C. GRIMM.

14A6L

Jefferson, Wis.

WOOD SEPARATORS!

PRICE LIST of the Besse Wood Separators: For the wide Langstroth frame, per 100, 50c; per 1000, \$4.00. They are of basswood, size 17½ x 35 x 1-16. Any size to order. Send 3 cent stamp for sample.

D. S. GIVEN & CO.,

HOOPERSTON, ILL.

W. Z. HUTCHINSON,

Rogersville, Genesee County, Mich.,

has made arrangements to receive Italian queens from the South, early in the season. The queens will be bred from imported mothers, reared by a thoroughly competent and reliable breeder, and, upon their arrival, they will be introduced to nuclei until needed in filling orders. These queens will be shipped as soon as it is warm enough in this latitude, probably about May 1st, and they will be used in filling all orders for untested queens until about June 15th, when queens reared in the home apiary will be ready to ship. Before June 1st, untested queens will be \$1.50 each; during June, single queen \$1.25, or six for \$6.00; after July 1st, single queen \$1.00, six for \$5.50, twelve for \$10.00. Tested queens (reared last season in the home apiary), before June 1st, \$3.00 each; during June, \$2.50 each; after July 1st, \$2.00 each. Safe arrival guaranteed. Make money orders payable at Flint, Mich. 14D1f

The Excelsior Smoker Co.'s Cold Blast gets away with all of 'em. You can handle the most vindictive colony without veil or gloves. Send us \$1 and try it. By mail, postpaid. Address W. C. REMP, Manager, Orleans, Ind. 14D3f

FLAT-BOTTOM COMB FOUNDATION,

OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

VOL. XIX.

CHICAGO, ILL., APRIL 11, 1883.

No. 15.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Apis Dorsata, the Bee of Java.

Mr. Jacob Kefmer, of Lowell, Mich., on March 26, 1883, writes as follows :

"I send you a slip from a local paper with the following description of a new kind of bees, which I would like to learn more about, and if they would do in this country. Please answer through the BEE JOURNAL."

"In perusing a late publication on the Eastern Archipelago, we find that the writer describes as one of the curiosities of the Island of Timor, distinct species of wild bee, the *Apis dorsata*, as abounding there in great numbers. He says : "These bees construct the most remarkable and colossal honey combs, suspending them from the under side of the loftiest branches of the highest trees. In shape they are semi-circular, and their diameter is frequently 3 or 4 feet. Their wax is one of the principal exports of the island." Here is information for the American apiarists to act upon; for an importation of the above might be found very advantageous to their industry. The Timor bee might prove to possess a longer proboscis than even the Italian, or some other quality which would make it more profitable to be kept than any of the various species we now possess."

We have very often described the bees found in the Islands of Timor and Java in the East Indies, but as our correspondent, with many others who are reading the BEE JOURNAL this year for the first time are not familiar with them, we will give a very brief description.

Mr. Wallace, the celebrated traveler and author of "The Malay Archipelago," thus relates his experience in those Islands with the *Apis dorsata* :

"On examination I found them half as long again as *Apis mellifica* and

their brood comb proportionably thicker. They were, in fact, a variety of the magnificent *Apis dorsata*, which is described as flourishing abundantly throughout the great Indian peninsula, from Cape Comorin to the Himalayas, as well as in Ceylon."

"In Borneo and Timor the wax forms an important article of commerce. The combs hang on the under side of horizontal limbs of lofty trees, often 100 feet from the ground. I have seen three together as above, and they are often 4 feet in diameter. The natives of Timor I have seen take them. They climb up a tree carrying a smoke torch made of a split creeper bound up in palm leaves, and hanging by a rope from their waist. They cover up their body and hair carefully, but their arms and legs are bare. The smoke directed on the

the East is one at Malacca; the natives hang up bamboos and hollow logs for it, but it is, I believe, not a true *Apis*, as it makes clusters of large oval shells of black wax."

Mr. Frank Benton in 1880 visited the Islands of Timor and Java in search of *Apis dorsata* and *Apis Zonata* but was not rewarded by securing any to transport to America. A very interesting detailed description of his journey was published in the BEE JOURNAL for May 11, 1881. We have no idea, however, that they would prove of any value to American apiarists; the only result would be the securing of a novelty; their ferocity and ability to inflict terrible wounds

Manner in which Bees in Borneo and Timor build their combs.

comb makes the bees fly off in a cloud as the man approaches. He sweeps off the remainder with his hand and then cuts off the comb with a large knife, and lets it down to his companions below by a thin cord. He is all the time surrounded by a cloud of bees, and though the smoke no doubt partly stupefies them, he must be severely stung. While looking on from a considerable distance, a few came down and attacked me, and I did not get rid of them till I was half a mile from the place and had caught them all, one by one, in my insect net. The sting is very severe. I should imagine that in Timor the dry season answers to our winter, as the drought is very severe and much of the foliage is deciduous. Eucalypti are the most common trees, and their flowers, I suspect, supply the bees with their honey.

In Borneo combs are placed in a somewhat similar manner, perhaps formed by the same species. The only bee I have seen domesticated in

by means of their enormous stings, is horrible to contemplate.

The thoughtful and prudent apiarist will now be making arrangements to provide pasturage for his bees, if he is not already in possession of it. The time will soon be here to sow seeds of honey producing flora of all kinds, and to plant out basswood trees. Let no time be lost in making full provision for the bees, and then we shall hear no more of "blasted hopes;" but instead of it, the songs of the apiarists and the "merry hum" of the "busy bees" will vie with each other in making glad thousands of homes, scattered all over the country. This is a "seasonable hint," and one that should be heeded at once, for this is "the accepted time."

CORRESPONDENCE

For the American Bee Journal.

Stimulating Bees in Spring.

G. M. DOOLITTLE.

I am requested to write an article for the BEE JOURNAL on "Stimulating bees, so as to get them ready for the white clover honey harvest." In my opinion there is nothing gained by commencing too early, as from six to eight weeks is sufficient time to build up a fair colony in spring, to one sufficiently strong to store honey to the best advantage. As clover usually begins to yield honey, in this locality, about June 15 or 20, the first of May is soon enough to commence to stimulate brood-rearing. Some think it does not pay to change the brood combs, by way of reversing them, putting combs of honey in the centre of the brood nest, etc., but after years of experimenting, I am satisfied it pays *me*, whether it does others or not.

Before telling how I manage, I will describe one experiment. I tried, to see if it paid to try to build the bees up in spring faster than they would naturally do it themselves; for, on this matter of *pay* rests nearly all there is of bee-keeping, to the average apiarist. One spring, several years ago, I set apart 10 colonies, all of which had plenty of honey, and were as near alike as possible, to obtain 10 colonies of bees. After seeing that all were in proper condition, 5 were left to themselves, and the other 5 worked according to the plan I shall describe. The 5 let alone were 2 weeks behind the others in swarming, and, upon footing up in the fall, I found they only gave an average of $\frac{2}{3}$ as much honey as the other 5 which were stimulated. From this and many other experiments I have tried, I conclude it pays, and so attest my faith by adhering to that which gives me the greater profit.

About the first of May I go over the whole yard and examine each hive to see how much brood there is, and all colonies which do not have an equivalent to $2\frac{1}{2}$ frames full, are shut up upon the frames of brood they do have, by means of a division-board; while those which have that amount, or more, are allowed the whole hive. At this time these last-named colonies have their brood nest reversed by putting those frames, having the least brood in them, in the centre of the cluster, and those having the most at the outside, thus causing the queen to fill these centre combs with eggs as fully, or more so, than those were which were in the centre before; while the brood in those now outside is not allowed to decrease at all. Thus quite a gain is made, with little danger of chilling any brood. In about a week I take a frame having considerable sealed honey in it, and break the sealing to the cells, by passing a knife flatwise over it; then,

after spreading the frames apart, place this in the centre of the brood nest. The removal of this honey by the bees, causes them to feed the queen, and stimulates brood-rearing, equally as much (in my opinion) as any other method of feeding. If I did not have the frames of honey I would fill empty combs with sugar syrup, and use the same as frames of honey. As the honey is removed, the queen fills the cells with eggs, and at the end of another week another frame is added in the same way. The next time over, the brood is removed as at first, while, at the end of the fourth week, two frames instead of one, are placed in the centre of the brood nest, leaving one or two frames of brood between them. This brings us to near the first of June, and if one colony has brood in four frames at the time of commencing, and we use 9 frames to the hive, we have but one more frame without brood in it in the hive. The next week this is placed in the centre, and as soon as the bees get any honey, more than to feed the brood, the boxes are put on.

Those weaker colonies shut upon the frames, having but little brood, are left so till the frames are well filled with brood, when they are given a frame of honey in the centre, and then manipulated as were the others, till they are in the same condition. If I wish as many colonies as possible, I begin to take brood from those having their hive full first, and give to the strongest of these weak ones, and later, to the next strongest, till all are built up to strong colonies. I formerly gave these frames of brood to the very weakest first, but after losing several frames of brood, I learned that to give a frame of brood to a very weak colony of bees, before settled warm weather, was almost always sure to result in loss.

If I wish honey instead of increase, I work all the weaker colonies till they have 5 frames of brood each, when 4 frames of brood, bees and all, are carried to another and united with it, while the frame having the queen upon it, is placed back in the hive again. The 5 frames in the hive we wish to unite the 4 frames of bees with, are spread apart, and the 4 frames placed in each alternate space, so as to prevent any quarreling, as bees, thus mixed, seldom quarrel or harm a queen. In two weeks this united colony will be as strong as any in the yard, while the frame having the queen, can be used for a nucleus, or various other purposes. In this time of high prices of comb foundation, they could be made very profitable by setting them to building comb, for they are almost always sure to build nice straight worker comb.

In places where pollen is scarce, it might be well to feed rye meal, early in the season, but, as long as plenty of pollen remains in the comb, I do not think it pays. To feed, place in a shallow box and drop a few drops of honey on the meal, when you will put a bit of comb on a hot iron to make a smudge, to draw the bees. Use only a few drops of honey, or you may excite robbing. I would invite all those

who do not think that the above will pay, who live where a crop of clover honey is to be secured, to try a few colonies, and see if they do not change their minds.

Borodino, N. Y.

For the American Bee Journal.

Comb vs. Extracted Honey.

A. W. STITH.

There seems to be quite a diversity of opinion in regard to producing comb and extracted honey. I have had some experience in producing both, and can probably say something that may be a benefit, especially to the amateur. The idea, that honey extracted before being capped by the bees, has all the good qualities of honey that is capped before extracting, does not meet my approbation. I am so thoroughly convinced that honey extracted while green, is inferior to honey capped before extracting, that I do not expect to extract any more green honey, unless in cases of emergency, when bees are gathering rapidly and have not sufficient combs to store their precious sweets; and right here let me say, that a too free use of the extractor is one reason why many bee-keepers complain of not having surplus combs. All apiarists know that bees will not build comb, to any great extent, only as instinct teaches them it will be used for storing honey, therefore, bee-keepers should not expect their bees to build comb, and at the same time keep the combs they already have empty, by the use of the extractor.

The judicious use of the extractor is more than merely to learn how fast you can sling the honey, and leave the bees to starve the following winter! While I am free to admit that the extractor is indispensable in an apiary, I do think that, all things considered, extractors kill as many bees as they help to produce.

Do not understand me to accuse an experienced bee-keeper of such blunders as to kill bees in such a manner, but as there are many persons just embarking in the business, I thought a word of caution would not be out of the way and may be appreciated.

When we examine an apiary in autumn, worked for extracted honey, where we use a two-story hive, and when we wish to supply our bees with food for their long winter nap, we find the honey in bad shape for winter, the combs in the brood-chamber often being destitute of honey, and contain much pollen, while those in the top story are sure to be full from top to bottom, or nearly empty. Such has been my experience.

I learned, several years ago, to be rather timid with the extractor, and settled down on the following plan: When white clover, which is our main dependence for surplus honey, fairly opens, I select, in the top story (for I seldom bother the brood-chamber for surplus), 5 or 6 Langstroth frames of the best worker combs, if they can be obtained; if not, a few drone combs can be used, and mark the letter W

(which signifies winter) on the top bar; put those combs near together, and do not extract from them. As soon as the honey in those combs are sealed nearly half way down, I spread them apart, and insert in each alternate space an empty frame, or one partly filled with comb or foundation, and the frames thus inserted can, as fast as completed, be extracted at pleasure.

I thus secure three objects: A hive full of straight comb; the queen is forced below, on account of the frames marked containing much honey and being far apart, and the rest of the combs, as fast as completed, are filled with honey, having a nice lot of sealed clover honey for winter.

But here comes the trouble. Empty combs will not do to winter bees on, neither do I believe full frames of honey, without some empty cells, much better, in this latitude; but when we produce comb honey, the honey in the brood-chamber is in a much more desirable shape. I believe I am the only one in this part of the country that produces comb honey, and being requested, by some of my neighbors, to write my plan of manipulating sections without separators, I cheerfully make the effort.

I use the Langstroth hive exclusively, have used both 8 and 10 frames, but have no use for 10 frames beneath a rack of sections, as I use a rack similar to a crate, with partitions between the rows of sections.

The first thing, after the sections are on, is to get the bees to work in them; for Italian bees are very loath to enter boxes. The best method that I have ever practiced, is to use 10 frames in the brood-chamber until the bees are strong in number, and ready for the boxes; previously to adjusting the boxes, I remove all but 7 or 8 frames, and use a division-board on each side of the frames, so arranged as not to allow bees behind them. The hive having, heretofore, been crowded with bees to its fullest capacity, and by contracting the hive inside, the bees are compelled to take possession of the boxes immediately, or cluster outside the hive. As the bees are not desirous of swarming yet, and as the honey harvest has just commenced in earnest, they are most likely to work in the sections. Now, having the boxes on, with a starter of comb or foundation in each section (the former preferred), and after the bees have been at work in them a few days, probably they may need some attention. I usually examine each section twice a week, and this is the main secret in obtaining straight combs without separators, for we are sure to find some probably half finished, whilst others near them are just commenced. Take out all the sections that are nearest completed, and put them together, and thus always keeping the fullest together, and the ones least worked in near the lean end of the row. I think I got that "lean end" from Mr. Heddon (thanks to Mr. Heddon). If any of the sections are nearer completed on one side than on the other, put them with their fullest

sides together, or near the glass at the end of the row, but leave space between the honey and end of the box, sufficient for the bees to pass, or they will empty the honey from the outside and carry it to the other sections, which is only a loss of time, and the hives are level from right to left, and if I follow the above plan, I seldom have to bend or cut a piece of comb, although if I cut a bit of comb out, it is not lost, but will make a nice starter for another section. If not quite so cheap as foundation, it is much better.

Perhaps some may think that honey produced without separators would not be nice enough for the Cincinnati Industrial Exposition. But I will say that, with my experience in the production of comb honey, and a few acres of (melilot) sweet clover, I was able to procure just such honey as Dr. Miller and others saw there last fall.

I believe my honey was all the comb honey that was there. What in the world is the matter with bee-keepers around Cincinnati? If correspondents of the various bee papers would write less about half-pound sections, yellow bees, etc., and more about practical experience in the production and sale of pure honey, and try to create a better demand at home by making better displays at their county fairs, and sell only such honey at home or abroad as they can fully warrant, we would certainly do the greatest good to the greatest number.

Dividing Ridge, Ky., Feb. 23, 1883.

For the American Bee Journal.

Description of My Bee Room.

U. E. DODGE.

I have 42 colonies in the cellar, and 19 packed on the summer stands. Those on the summer stands had a flight on Feb. 17, the first since Nov. 15. The thermometer showed 65° in open air, 48° at the top, and 45° at the bottom, in the cellar. No signs of dysentery in the cellar or on the summer stands. The lowest range of mercury, this winter, was 9° below zero. Last season was poor, in this locality; no surplus, and very little natural increase. This is my first year's experience in cellar wintering. My arrangements were as follows: I have a room, 10x12 feet, partitioned off in one corner of the main cellar, which is thoroughly plastered, on two sides and bottom, with hydraulic cement; the other two side walls are made of matched boards and battened. I have a tight-fitting door from the main cellar, and in close proximity to my outside cellar-way, through which I enter the cellar below, down five stone steps to the cellar bottom. From the bee room, I have a 3-inch glazed tile pipe, running through the cellar wall, 3 feet under ground, running horizontal about 8 feet; on the end of this pipe, I have an elbow which turns the pipe up, at right angles with the pipe, that runs through the wall, from the cellar, leaving the end of the elbow sticking out of the ground about 6 or 8 inches. I have a wooden tube,

6 inches square and 8 feet long, made of matched pine boards and painted, with galvanized iron, one-half circle, on top, to keep out the storm and give room for free circulation of air, with a damper to shut off the outside air, when desirable. This wooden tube I place over the end of tube-pipe, in a perpendicular position, holding it in place by hooks and staples, attached to the outside covering of the cellar door, and earthed up snugly around the bottom or base of the tube; the damper completely controls, and I find I can add or diminish the volume of outside atmosphere at pleasure, which gives complete control of the temperature of the bee-room, at any time, when the weather outside is colder than the ordinary temperature of the cellar. To control the inside atmosphere of bee-room, I have a 2½ inch tin pipe, connected with the room, on the opposite side from the tile pipe, and running through the floor of the sitting room, which is directly over the bees, connecting with the stove pipe above, in that room. In the pipe is a tight-fitting damper, which I can use at will, checking or increasing the draft of air from the room through the chimney.

I have two thermometers in bee cellar, one hung near the bottom and one near the top. It has not, this winter, been lower than 42°, nor higher than 49°, since Nov. 15, the day I put the bees in the cellar. In the sitting room and directly over the bees, stands an anthracite coal fire, constantly burning, night and day.

To further control the temperature of the bee-room, as the weather becomes warmer and spring advances, should the bees show signs of uneasiness, I have secured a quantity of ice and propose to remove the upright wooden tube which fits over the end of tile pipe, leaving the end of tile sticking above ground, about 6 or 8 inches. Over this I propose to set a box with a hole in the bottom, just fitting over the tile, leaving the end of the tile tube sticking up inside of the box; this box is supplied with a tight-fitting lid, that may be opened or shut, at pleasure. In this box I intend to put ice from day to day, as required, in sufficient quantities to cool the air that passes through the tile pipe into the bee-room, to obtain the desired temperature from day to day, until I deem it proper time to set my bees upon their summer stands, say about the blooming of soft maple.

There does not seem to be the slightest moisture in the bee-room; the quilts seem as dry as the same material would be in an ordinary room. The bees seem perfectly at home, and, to all appearance, in a happy and contented mood. How long they may so continue, is a problem that I am unable to solve at present; but the prospect is certainly flattering, and I hope reflections from "the silver lining," may penetrate and cheer the hope of every genuine apiarist of the land.

If the theory and practice of damp cellar wintering is correct, I am certainly on the wrong track, and in the opposite extreme. My cellar is so dry

that I can hardly brush the floor without raising quite a dust. There has not been three days in succession this winter, that I have not seen my bees in the cellar, making my observations quite short, but, most invariably, turning back the quilt of one or more colonies, which does not seem to disturb them in the least.

My experience in out-door wintering, in the past, has led me to believe that one important factor in successful wintering, is to keep the bees dry, and I fail to comprehend why removing to a cellar should so much change the nature and constitution of the bees, that it should require an entirely opposite state of things. To admit, when convinced, is one of the most noble traits of character, and should I find, by more extended experience, that I am pursuing the wrong theory, to the injury of the bee-keeping fraternity, then I shall acknowledge the error.

My ice proposition is merely theoretical, and should I be on the wrong track, and in danger of injuring my bees, will some one notify me through the BEE JOURNAL before it is too late, and the injury is done. Also state the extreme limit that it will do to keep bees in the cellar, when put in Nov. 15. I wish to keep mine in as long as possible, and not overdo it. I have a quantity of candy, ready for putting on my hives, if necessary. Can I put it on in the cellar, should any need feeding?

Fredonia, N. Y.

[If the bees remain quiet, when the maples, willows, etc., furnish pollen, will be time enough to put them out on the summer stands. You can put candy over the frames, at any time it may be necessary, and they will readily take it.—ED.]

For the American Bee Journal.

The Half-Pound Sections.

JAMES HEDDON.

It seems to me that some of our fraternity are losing faith in the practical good sense of bee-keepers.

One says, if we adopt the half-pound section, it will ruin the business. Well, then, my faith in our folks is thus great that I really think they will not adopt them, or do anything else, that will "ruin" ourselves. If half-pound sections have connected with them, and their use, an expense which costs more than the consumers' increase of demand is worth, then those who tempt the little Tarantulas, will be the first ones to be bitten.

Mr. Baker speaks as though it were inconsistent for me to have first cautioned against their use, and then assert that I was going to use a few thousand of them. I made up my mind to this: if there is a demand for this size, no individual or organized efforts can stop a catering to that demand. I put in a word of caution, hoping to induce others to touch them lightly, and in a less expensive way, than last New Year's boom might

lead many to do; that boom is now over. A corresponding reaction has taken place, and I think it expedient that some, who are the best situated so to do, and whose experiments are sought after from time to time, should experiment with and settle the question, here in the West, by the argument of experiment between the producer and consumer.

I have carefully read all the articles I have seen on the subject (I take nearly all the bee papers), and, as yet, I have gotten little light regarding the wisdom of producing comb honey in half-pound packages. I fancy I discover an under current of a fear of competition, in many articles. This argues in favor of the adoption of the half-pound section. When I changed from two to one-pound sections, I was told by many writers that I need not expect as many pounds of honey. I have taken no less with one than with two-pound sections, when using them side by side. I think I know the reasons why. These reasons give me full assurance that I will realize just as many pounds with the use of half-pound sections as with any larger size. My bill for sections will be doubled, and the labor of manipulation will be increased. Between this and the extra price, and sure, safe transportation of the small sections, I shall be left to decide.

Does it not seem strange that bees cannot work readily in a space $4\frac{1}{4} \times 2\frac{1}{2} \times 16 \times 12$, in the half-pound sections when they "do not object" to a space $4\frac{1}{4} \times 4\frac{1}{4} \times 12$, with tin side walls at that? Have they an idiosyncrasy against the sound of "half-pound"? I first said, and say now, "go slow." Do not go to any undue expense to rush into the new, till you have more reason to think it enough better than the old, to pay for so doing. I shall not adopt the small sections to the displacement of my one-pounds. I can mix them with one-pounds in my experimental supers, and in my shipping crates, and use or refuse them without any alteration or fixtures, and I mean to be able to truthfully talk more positively upon this subject ere another year rolls around.

Please let me say to Mr. Newman, of Ohio, that I will "unload" regarding our winter diseases of bees as soon as my last chance for 1882 and 1883 experimenting is over.

Perhaps a short item will do for the subject of "Light in bee repositories," referred to on page 140, by yourself and Mr. A. P. Fletcher. Please tell your mechanical acquaintance that death is as natural as life. That nature, with her infinite arms, embraces all that can be imagined by the mind. Nature is at war with itself. Most things thrive at the expense of other's premature death, and man is found in either class, viz.: the consumer and consumed. Animal and vegetable beings thrive better, when assisted in the struggle, by the wisdom of man; whatever bees "naturally" do, may or may not be the very best or worst thing they can do for the perpetuation of their existence. Evolution is the only key that can unlock the many mysteries just coming into view. It

is the great truth that underlies all other truths, and is now dawning upon the common mind throughout the world. It has been demonstrated that bees can, in cellars as in "trees in the woods," winter well with light enough to tell potatoes from apples, but it has also been found out that an advantage is gained by changing this "natural" condition of affairs, and keeping them free from all irritating influences; among which is light, as well as the activity forced upon them from the extreme low temperatures of our winters. None of these are, however, the real cause of dysentery.

Dowagiac, Mich., March 30, 1883.

For the American Bee Journal.

My Observation Hive.

W. HARMER.

I use the Heddon hive, as will be seen by the engraving. As an observation hive, it can have any number of Langstroth frames, from one to seven; the sides are movable, and can be taken out, as they slide down in grooves, and glass can be put in

Heddon's Observation Hive.

the grooves instead of the wooden sides, making an observation hive. It is a very simple hive to make, and I think every bee-keeper should have an observation hive. I would not be without mine for considerable. It is an endless source of pleasure to me.

Manistee, Mich.

Western Maine Convention.

The bee-keepers in Southwestern Maine met at the residence of Mr. J. B. Mason, Mechanic Falls, Maine, on Wednesday, Feb. 28, 1883, at 1 o'clock p. m., for the purpose of forming an Association.

The meeting was called to order at the appointed time, and W. W. Dunham, of North Paris, was chosen temporary chairman; after which, communications were read from Messrs. Wm. Hoyt, of Ripley, secretary, and F. O. Addition, of Dexter, president of the State Bee-Keepers' Association; also from Mr. H. B. Cony, of Augusta. Following these, Mr. J. B. Mason, of Mechanic Falls, presented a paper, and it was voted to have it published in the *Apiarian*. These communications were read carefully and considered by all present.

A permanent organization of the Western Maine Bee-Keepers' Association was made, and the following officers were elected for the ensuing year: President, Dr. J. A. Morton, Bethel; Vice-President, J. B. Mason, Mechanic Falls; Secretary, W. W.

Merrill, Mechanic Falls; Treasurer, W. W. Dunham, North Paris. Committee on Constitution and By-Laws, W. W. Dunham, J. A. Morton and J. B. Mason.

A constitution and by-laws were adopted. The first article of the constitution defines its name as the Western Maine Bee-Keepers' Association.

An article in the by-law provides, that any person can become a member by signing the constitution, and paying the sum of 25 cents; ladies, simply by signing the constitution.

The Association starts out with 20 members, 18 males and 2 females, representing 145 colonies of bees. The object of forming this Association was to advance bee-culture in this western part of Maine, and in no wise to injure the State Association, and we would like all to join this, as well as the State Association.

A vote of thanks was tendered to Mr. Mason and family, for the kindness bestowed by them.

The next meeting will be held on Wednesday, April 25, 1883, at the residence of W. W. Dunham, North Paris, Maine, at 1 and 7 p. m.

W. W. MERRILL, Sec.

For the American Bee Journal.

Narrow vs. Wide Frames for Sections.

J. G. STEEL.

On page 144 of the BEE JOURNAL, for March 14, T. E. Turner writes concerning wide frames for holding sections: in which he gives some very plausible objections to their use, as I have fully learned from experience. The principle one, namely, the difficulty in removing the sections from wide frames, I have been trying to overcome, and as a result have made a narrow frame both to hold sections and to answer the place of a division-board, in winter, for chaff. I do not know that I can make the description of it plain to the readers of the BEE JOURNAL, but I will try.

The frame I use is the Gallup, to hold 4 sections, $5\frac{1}{4} \times 5\frac{1}{4}$; inside measure, $10\frac{5}{8} \times 10\frac{5}{8}$; outside, $11\frac{1}{4} \times 11\frac{1}{4}$. Instead of the wide frame, I make a frame to fill the whole space of the inside of the hive, viz.: 12 inches, and only $\frac{1}{2}$ inch wide. I cut the side bars out of $\frac{1}{2}$ inch stuff, and 11-16 thick, and reaching clear to the bottom of the hive. The bottom bar is the same, and 12 inches long; to be nailed to the side of the side bars even with the bottom ends of the same, instead of to the end. I use an ordinary top bar of the frame, for the top, letting it project over $\frac{1}{2}$ inch, on one side, and the other being even. On the side which projects over, I nail the bottom bar, which will also project $\frac{1}{2}$ inch, and is to hold and support the sections.

Previous to nailing, I slot the inside of side bars, the whole length, with a $\frac{1}{8}$ inch slot, 3-16 deep, and $\frac{1}{8}$ inch from the edge. Be careful in nailing to make these slots come nearest to the edge of the side of the frame that is even. The slots are for $\frac{1}{8}$ inch wood separators. These can

be slipped in at bottom of the frame after it is nailed, as will be seen, the bottom bar being on the other side, it will not interfere with their insertion. The separators will stay just where you put them.

Now you have a frame, with bottom bar reaching nearly half-way, or $\frac{3}{4}$ inch across the bottom of the section, which, with $\frac{1}{2}$ inch at the sides, and $\frac{3}{4}$ at the top, is sufficient to keep the sections in their places, and allow of their removal with ease. Set the frame, filled with sections, in the end of the hive, with the naked edge of the sections next to and close against the end of the hive; then the separators will come next to the brood. If desired to put two cases or frames of sections at the side of the brood, the second set of sections will slip up against the separators, and into the frame of the first set, as will be seen, $\frac{1}{8}$ of inch.

The advantages of this frame are: It allows of easy manipulation, as it fits neatly in the hive; it will stay in its place, and prevents the bees from getting at the outside of the sections to stick them over with propolis.

It serves as the very best kind of a division-board for chaff packing, as the thin separators and bee spaces admit of a more ready absorption of moisture. They can be used in the upper story in the same manner as two at the side.

I would say to Mr. Turner I always make my upper story to admit division-board, after being filled with frames of sections, which, when removed, allows of free access to the frames of sections.

If I have succeeded in making the principle plain, any one can adopt it to their different size of hives. Some may prefer a wider bottom bar, to support the sections. Such can use $\frac{5}{8}$ or $\frac{3}{4}$ inch lumber, which will still allow enough of section to project for a "finger hold." I prefer about $\frac{5}{8}$. If there is any merit in the thing, all may freely use it.

Queen Rearing—The Lamp Nursery.

W. Z. HUTCHINSON.

Queens having now become quite a staple product of the apiary, perhaps two or three articles devoted to the subject may not be amiss; although, as Mr. Doolittle said in regard to the excellent articles that he gave us last year upon comb honey; "what I write will necessarily be somewhat of a repetition of what I have already written."

The first step for the would-be queen breeder is to Italianize not only his own bees, but all the bees within, at least, three miles of his own apiary. The demand, at present, for pure Italian queens, that are purely mated, is such that a queen breeder cannot allow black bees in his neighborhood. In regard to the strains of Italians that he will breed from, each one must decide for himself. I prefer the dark Italians. I do not wish to say

that there are no good honey gatherers among the light Italians, but, among the several different strains of light-colored Italians that it has been my fortune to try, none have equalled any of several different strains of dark Italians that I have owned. Honey production, hardiness, amiability, and color should be bred for, in the order named, but I fear that some breeders have bred in the reverse order. I say nothing about the Cyprian and Syrian bees, because, from experience, I know nothing of them.

For breeding stock from which to rear queens, no pains nor expense should be spared to obtain the best; and, as probably the majority of the queens will mate at the home yard, equally as much care should be taken in obtaining stock for the protection of drones. Selection of stock for the protection of drones is a point that, I think, has been too much neglected. After the apiarist has furnished his own apiary, and that of his neighbors, with choice stock, he is ready to commence the rearing of queens for others.

Although objections have been raised against the hatching of queens in a lamp nursery, yet the majority of breeders hatch their queens in this manner; in fact, it would be well-nigh impossible to rear queens at the present popular prices without the aid of the nursery. During the past five years I have had queens hatched both in the hives and in the nursery, and I have never been able to discover that hatching a queen in a lamp nursery enfeebled her constitution or anything of the kind. I can detect no difference between queens hatched in a nursery and those hatched among the bees. A lamp nursery need not be a complicated affair—just simply a box with double walls of tin, and large enough to allow several frames to hang inside. A hole should be made at one of the upper corners to allow the space between the walls, which should be about $\frac{3}{4}$ of an inch, to be filled with water. A round hole, perhaps an inch in diameter, should be made through the walls of the bottom, at the centre, and also through the side walls of each side, and a tube of tin soldered in each hole, thus fastening the walls together so that they will not bulge when filled with water. The tin tubes can be covered with pieces of tin, so that the queens cannot crawl out and become lost. The nursery should be fastened in the top of a tall box, the top of the nursery being level with the top of the box. In order that the heat from the lamp below may circulate all around it, there should be a space of an inch between the sides of the nursery and the inside of the box. Strips of wood, an inch square, can be crowded in between the upper edge of the box and the nursery, and the nursery furnished with a wooden cover hinged to one side of the box. To obtain the best effect, the box, in which the nursery is placed, should be of such a height that the bottom of the nursery is about a foot above the top of the lamp chimney. A thermometer should be kept in the nursery, and the temperature kept between 90° and 100°. If

the box is too tight or close, the lamp will not burn well. To save oil, and to protect the nursery from sudden changes of temperature, it is better to keep it in some building. If it can be placed in some room that can be darkened, and the light admitted through a small aperture, it will greatly facilitate the examination of queen cells about to hatch; as, by holding them up before the aperture, even embryo queens can sometimes be seen, especially when the cells are constructed of new wax. When there are many cells in a nursery, it requires close attention, otherwise a newly-hatched queen will destroy several cells. I have a brood frame, similar to those used for holding sections, divided into apartments about 2 inches square. This brood frame is covered with a sheet of glass on one side, and upon the opposite side, each apartment is furnished with a glass door that is hinged fast by pasting on a strip of cloth for a hinge. Each door is kept closed by a little latch made by driving a common pin part way in, and then bending it over, so that it can be turned around over the door, or turned away when I wish to open it. This brood frame of apartments is kept hanging in the nursery, and about 9 o'clock in the evening, I examine each cell by holding it up before the lamp, and when I find a cell, the occupant of which appears nearly ready to commence biting her way out, I place it in an apartment by itself.

Some breeders have only one nucleus in a full sized hive, while others make a small hive for each nucleus, and use it for no other purpose, but, to my mind, it is better to use full sized hives, putting two nuclei in each hive, and keeping them separate by using division-boards. These division-boards can be made very cheaply by using $\frac{3}{8}$ lumber, tacking a strip of wood across each end to prevent their warping, and then tacking a strip of enameled cloth over the edges, not drawing it uptight or close against the edges of the boards, but allowing it to point out so that it will form a sort of tube all around the edges of the boards, and this yielding tube will fit any inequalities there may be in the sides of the hive.

For a stand for the hives I use a board a little larger than the bottom of a hive, with two cleats nailed underneath each end to prevent it from warping and to raise it from the ground. To furnish each nucleus with an entrance, I turn the hives around upon its stand until two diagonally opposite corners project beyond the edge of the stand or bottom board sufficiently to allow the bees to pass under the edge of the hive. Three-eighths of an inch below each entrance, to the edge of the bottom board, I nail a small piece of board, 3 or 4 inches square, to furnish the bees with an alighting board. Queen registering cards are a necessity, as they show, by the position of the pins upon their dials, the date of the last examination, and the condition of the nucleus at that date—something that the memory could not do.

Queen rearing nuclei need to be examined quite often, and when the hives are placed upon the ground, so much stooping becomes tiresome; for this reason I have a large share of my nucleus hives perched upon stakes, at such a height that they are convenient for manipulation while I am standing upon my feet. I also have the covers hinged, so that they can be turned back, thus forming convenient shelves for the smoker, queen cages, box of comb containing larvæ, etc., etc. There are also two sticks tacked to the sides of each hive, and these sticks project a few inches beyond the end of the hive; and upon these projecting ends I can hang combs while caging queens.

Rogersville, Mich.

New Device for Sections.

THOMAS CANNY.

I send you a drawing of a section that I shall use this season. This kind of section originated with me, I believe, as I have never read or heard of such being in use. It is cheapness, utility and convenience combined, in obtaining surplus honey in one-pound or half-pound sections, doing away with extra cases, racks, brood frames,

etc. The apiarist can obtain his surplus honey in either half-pound or one-pound sections, and the honey stored in both at the same time, by this device. If you want to get pounds, cut only one kerf on both top and lower bar, of either top or lower tier of sections.

With a nailing apparatus it can be put together as quickly as 3 one-pound sections. Please put it in the BEE JOURNAL for the benefit of all beekeepers. It is not patented.

East Poultney, Vt.

For the American Bee Journal.

Inspectors of Apiaries.

J. E. PLEASANTS.

DEAR EDITOR:—Inclosed find a bill introduced in our State legislature at its last session, and which has become a law. What is your opinion of such a law? I favor it. The rainfall up to date is 6½ inches.

Carbondale, Cal., March 24, 1883.

A bill has been introduced in the Assembly, by Mr. Reeves of San Bernardino, to authorize the Boards

of Supervisors of the several counties of this State to appoint inspectors of apiaries, and provide for their compensation, and defining their duties, and for the further protection of bee-culture. The bill has the concurrence of the representatives from San Diego county. It provides as follows:—

SECTION 1.—The Board of Supervisors of any county wherein bees are kept, are hereby authorized to appoint one or more persons as inspectors of apiaries, to hold office during the pleasure of said Board.

SEC. 2.—The Board of Supervisors shall fix and determine the compensation of the inspectors of apiaries to be paid out of the funds of the county, not otherwise appropriated.

SEC. 3.—Upon complaint being made to the inspector, to the effect that, in complainant's opinion, the disease known as "foul brood" exists in any apiary in that county, it shall be the duty of such inspector to inspect such apiary as soon as practicable, and direct the person in charge thereof to destroy all hives ascertained to be so affected, together with the combs and bees therein, by burning or burying the same in the ground the following night.

SEC. 4.—If the owner or person in charge of an apiary, by his own inspection or through any other source, discovers foul brood in any hive in said apiary, it shall be his duty to destroy such hive and contents in the manner provided in section 3 of this Act.

SEC. 5.—Any persons failing to comply with the provisions of the last section shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than 5 dollars nor more than 25 dollars for the first offense, and by a fine of not more than 50 dollars for each such subsequent offense.

SEC. 5.—This Act shall take effect from and after its passage.

[We think such inspectors will be beneficial, if they attend to their duties.—ED.]

For the American Bee Journal.

Getting Candied Honey Out of Combs.

W. H. B.

I have been experimenting, for several years, to find out the best way to get candied honey out of the frames. In fact, I have experimented away many dollars, for I wanted to get it out in a hurry, and I have made several things for the purpose, which it is useless to describe, and wasted more than a few combs. About one year ago I thought I would try once more, and I was successful. I had a boiler made $\frac{1}{2}$ inch longer than my longest frame, $\frac{1}{2}$ inch wider than my shortest frame, and 5 or 6 inches deeper than the deepest frame. This will just let the longest frame in, lengthwise, and the shortest frame in crosswise. If you have an intermediate frame, you can lay a stick across the boiler; inside the boiler put a piece of tin,

doubled in the shape of an eaves-trough, and solder the edges to the boiler, just low enough to let the frames down below the top of the boiler. Then place the boiler on the stove and put in about 2 inches of water; make a hot fire and commence to uncap the honey; as fast as uncapped, set the frames into the boiler. When it is full, the first frames will be ready for extracting. If the honey should be very cold or frozen, or the honey is very hard, it may need to be set into the boiler the second time. With this boiler I can extract nearly as fast as when the honey is liquid. I use the boiler to carry the frames in; in the summer, to store frames in; also, in case of emergency, it comes handy to store unripe honey in. The boiler should be made of galvanized iron, so that it will be strong to handle.

Gazenovia, N. Y., March 31, 1883.

For the American Bee Journal.

How to Introduce Queens.

A. R. KOHNKE.

Onion! Asafetida!! Whew! Next comes stale eggs. I wonder that the bees did not leave their master and go to the woods where they had, at least, pure air, if nothing else. When I read the above suggestions in the JOURNAL, I intended to give the remedy I have used for several years, with perfect success, but other business preventing until I got the latest batch of German papers, in one of which (*Deutscher Bienenfreund*), is described a method by a German bee-keeper, Mr. Scheuerle, identical to my own, of which I give a condensed translation:

"After having lost and sacrificed many a nice and valuable queen, in order to discover a safe method of introducing them, I have, at last, hit upon a plan which has proven entirely successful. In order that a colony may accept a strange queen, five conditions must be fulfilled: 1. The colony must be queenless, nor should there be any queen-cells with brood or even eggs in them. 2. The new queen and the queenless colony must have the same scent. 3. The colony must be confused or bewildered. 4. All bees must be present at the operation. 5. The colony, with the introduced queen, must be kept in a dark place, say 24 hours.

"Some may think that the fulfillment of these conditions are very troublesome, which, in fact, is not the case. In order that you may not be detained, get everything you may need ready before hand. You will need the following: 1. Essence or extract of balm (*Melissa officinalis*), a small quantity to be had at the druggists. 2. A piece of woolen cloth, the size of a hand, and a small piece of cotton cloth, as also a strong quilt. 3. A tumbler. 4. A small piece of comb honey, but having no running honey about it. 5. A room with one window, which may be darkened.

"If you get the queen sent from a distance, she and the accompanying bees should be liberated in a warm

room, to void themselves; if the room is not warm enough, it must be made so.

"Now, suppose the shipper of the queen has sent you a notice of having mailed or shipped by express the queen you have intended to give to a certain colony, you will know about what day to expect her arrival. The evening before, when all the bees are home, take that colony into the room spoken of above, and see that no bee belonging to the colony leaves or flies off. Having received your queen and given her and the accompanying bees a flight, in another room, always keeping an eye on her, catch her again and put her with some of her companions under a tumbler, then take a piece of cotton cloth, put some of the extract of balm on it, and wipe the inside of a tumbler with it. Now take the bit of honey comb; put the queen and some few of her bees with her under the wiped tumbler, and let them remain there for sometime, or rather until you are ready to introduce her. If the colony, which is to receive the new queen, has an old one, that one should be taken away about noon, on the same day you wish to introduce another; but as soon as you get the colony into the room, moisten the piece of woolen cloth with essence of balm, and push it into the entrance of the hive, which is kept in the darkened room. If you get the new queen early in the morning, and, without delay, exposed her to the essence of balm, she will have acquired the scent by evening, otherwise she must remain under the tumbler till the next day.

"In order to better find the old queen, and also to confuse the bees, transfer the bees, comb and all, to another hive, looking carefully over each comb, as you remove it from the old hive, until you have found the old queen, which must be caught and caged, and then finish transferring the bees to another hive; the bees remaining in the old hive must be brushed out before the entrance of their new hive, and when they are seen to move in, the new queen is also put before the entrance, and will go in with the rest. Having done this with open shutters, and as near the window as possible, darken the room as soon as you see the queen enter the hive, to cause all the bees flying about the window to join the colony and let them stay there 24 hours, after which you may put them on their stand in the apiary.

"To re-queen queenless colonies, the apiarist must take such precaution as will suggest themselves, viz.: There should not be left any queen-cells in the hive, nor should there be a laying worker, which might cause trouble.

"The main principle is that the colony and new queen have the same scent, hence the perfume must be taken from one, and the same bottle for both. And to have something agreeable to the bees, is certainly preferable; hence, the odor of balm is better adopted to this purpose than anything else, for balm and a queen-bee have both the same name in the Greek language, viz.: *Melissa*; and

this, perhaps, on account of both having the same odor."

REMARKS BY TRANSLATOR:—Three years ago last summer, while making new colonies by dividing, I got two queens into one hive, getting an old queen by accident, or rather oversight, into a nucleus which I strengthened with some frames of brood and bees, spraying them with water of balm, as also the bees and laying young queen introduced into the nucleus. Both were laying the next day, when I discovered my old colony acting queenless.

Youngstown, O.

For the American Bee Journal.

Eucalyptus for Honey in Australia.

A. VERGE.

In a late number of the BEE JOURNAL, a bee-keeper, somewhere in California, reported a quantity of his honey crop to be derived from eucalyptus. It was a pleasant surprise to me to hear that one of our Australian trees had been recognized as valuable in that respect, in a country producing so many plants and trees of world-wide reputation; and though I do not suppose it will anywhere be found to yield such returns as are reported to be derivable from basswood, yet all its varieties will be found to be good honey producers, and valuable beside on account of the durability of their wood, which is especially well suited for the purpose of fencing, wharf piles, railway sleepers, etc., etc.

They will not, I think, flower much before the tenth year, but considering how very serviceable such wood will be, there is no tree, in my opinion, more deserving of being extensively cultivated, especially out in the prairie regions.

For both purposes, probably the best varieties are ironbark (*E. paniculata*); red or large leaved ironbark (*E. siderophloia*); or silver-leaved ironbark (*E. melanophloia*); bloodwood (*E. corymbosa*); stringy-bark (*E. obliqua*); blackbutt (*E. popularis*); and a species hereabouts called box, but the title of which I am ignorant of. It is the most, in fact the only, ornamental one of all, and is a fine shade tree, being frequently planted around Sydney in ornamental grounds; its timber, however, is not durable, being liable to dry rot. Blackbutt, again, does not grow beyond a few miles from the sea coast.

The honey secreted in the flowers of these trees has a fine flavor, though it is strong. There are still other varieties of the tribe indigenous to western Australia and south Australia, but I know nothing of their qualities. Here in latitude 31 south, they do not all bloom at or near the same time of year; ironbark and tallow-wood (another variety) begin in October, while bloodwood blooms from January to March, and near the sea coast where the frost is less severe, the country there being more thickly timbered, and consequently warmer. They begin a month earlier, and continue nearly a month later in flower.

I am but a novice in the use of the bar-frame hive, and, of course, I meet with frequent difficulties. I began only, last year, with 12 colonies of bees in Langstroth hives, procured of A. H. Newman, Chicago, at the suggestion of Mr. MacDonnell, of Sydney, to whom I am indebted for much valuable information on the mystery of the system. I had not used comb foundation long before I discovered that the adhesion caused by pressing the alternate strips cut in the edge of the sheet against the side of the triangular upper bar, after both strips and bar had been heated, was not sufficient to enable the sheet to support the mass of bees; as the bees invariably build out the middle and lower parts first, which were then filled with honey or brood before the top had been worked. I now fasten with hot wax, and have no further trouble.

1. Why do not the bees work out the sheet of foundation to the lower bar and attach it thereto? Is it because the frames hang too low; some of them leaving barely $\frac{1}{4}$ of an inch?

2. Why do they destroy the newly hatched brood? A great many were destroyed last month, though there was an abundance of clover and other honey plants in bloom; so many, in fact, that the ground below each box was quite covered with dead ones, and the smell of the decaying bodies might be felt at a distance. All the young bees that I saw being worried, were healthy looking and well formed; the destruction seeming to be common in those hives with wired foundation, and from which I had been taking cards of brood and cutting queen-cells in order to stop swarming. Two small colonies, which had received cards of brood, did likewise, although they had no queen-cells. Had it not been so in the latter case, I should have supposed that the slaughter was owing to my check on their attempts to swarm. Two other swarms, which have built out their own comb in empty frames, and which have not had their frames transposed, have not destroyed any.

3. What should I do towards the close of the honey yield with a hive having ten frames, chiefly of brood, and on which I have section boxes. If I remove the sections altogether, there will be little else than brood in the brood-chamber, and consequently no store for the hatching bees.

Quinby, at page 173, on boxing, says that "six combs are all that a hive requires when boxed;" but I have ten frames with eggs and brood in all. Ought I to remove some frames and confine to six only, as recommended, and then supply combs or foundation to the brood-chamber to be filled for their own use as the sections are removed. We have only frost here in winter, but flowers are quite scarce. My boxes are placed 10 inches apart, on a frame covered by a flat roof 6 feet wide; the frame is 15 inches from the ground, and rests on supports protected by pots of mixed tar and grease, without which, in this land of vermin, the black ants alone would kill every colony. They have sunshine before 9 a.m. and after 3 p.m.

From previous experience with bees in common boxes, I am quite certain that we shall get very satisfactory returns under the new order of things, in this locality; and I am, therefore, desirous of preparing to extend operations, and dealing with the industry as a business, though I have other means of dependence. In this view of the case, an assistant, at least, would be an absolute necessity; but the difficulty of meeting with any one possessing the requisite knowledge—no such person being obtainable in this country—is insurmountable.

Though I had always, hitherto, doubted it, I have now become satisfied that maize, too, must be included among the honey producing plants; by the direction of my bees flight, I know that a large proportion of the stores, now rapidly coming in, must be derived from it; besides I have watched them on its tassels when they were certainly searching for honey and not collecting pollen.

Mr. Editor, I send you some seeds of Australian trees; they are: 1. Blackwattle (*acacia decurrens*), the bark of which is valuable for tanning purposes. 2. Wattle (*acacia*). 3. Wattle (*acacia*). 4. Ornamental evergreen shade tree, a variety a pittosporum, a honey producer. 5. Eucalyptus, or *box* referred to before. 6. Australian forest oak; the wood of which was once extensively used for shingles. All of them will grow readily on the bare, hard ground, or on an ash bed that has been moistened and made solid by rain, provided they be dropped on top and pressed close; the soil being well shaded till they take firm hold, and kept moist when the air is dry. They will grow (except probably No. 4) on any poor clay or stone land; in fact, they are the hardiest trees known to us here; and will certainly not meet with more severe conditions of existence in America than in this country. I am not aware, though what extent of cold they can endure. East Kempsey, New South Wales.

[Having no place suitable for testing the seeds sent us by Mr. Verge, we have sent them to Mr. Heddon, who will, doubtless, plant them and report the results in due time. He also answers the questions thus:—Ed.]

As I sit here at my desk, on April 6, and the mercury nearly at the freezing point outside, my imagination carries me to the home of Mr. Verge, all sunshine and flowers, surrounded by the numerous blessings and evils that his more torrid climate affords, and I feel stealing over me a fear of incompetency to answer his queries as I wish I could; but from what I have learned by my experience here, I will say:

1. The bees partially recognize the bottom bars of the frames as bed-rock, and thus propose to pass over them when passing under their combs, and thus leave the space referred to instead of recognizing the space be-

low the bottom bars as a proper passageway. There should be $\frac{1}{2}$ inch space below your bottom bars, and we always make $\frac{5}{8}$ in our new hives, as $\frac{1}{8}$ is allowed for shrinkage.

2. There are a number of reasons why bees often drag out their pupa. If the surplus receptacles are not as they should be, they often do it to make room to store below, during an excessive flow of nectar. Again, you may have so placed the frames of brood you manipulated as to force the bees to cut a passageway between them, and thus destroy the pupa. I have used wired comb foundation for all the combs I have had built, for three or four years, and can assure you the wires do not in any way interfere with the success of the coming generation of bees. I have had (by careless handling) the wires rust and stain the foundation for inches each way, but all went as rapidly and successfully as before.

3. You should, in such cases as you mention, feed your bees with the cheapest wholesome food you can obtain. Cane sugar syrup is excellent. The dearth of the brood-chamber is more than made up by the increased amount of comb honey in the sections. The feeding is a very simple, safe, and practical procedure, when you once understand it, and are properly equipped. I would not encumber my system of management with any such removal of brood, and giving of frames of foundation. I not think it at all necessary.

The unsupplied and unsuppliable want of efficient help, you mention, is much realized in this country; also since honey production has reached its present proportions. My practical working school for apicultural student-apprentices, was inaugurated for the purpose of aiding in supplying that want, which, it is hoped, will be of mutual benefit all around. Of course, most of those who thoroughly and practically learn the business, will embark in it on their own capital; but some there are who must walk before they run, and some love travel and scenery in foreign lands, and by a year or two more we can send you a man who will not only "assist" you, but be of much service in bringing the latest practical "kinks" from the land of "Yankee invention." One who can manage your capital at a profit while you can do as you please.

I will do the best I can with the seeds. Many thanks to you and the editor.—JAMES HEDDON.]

SELECTIONS FROM OUR LETTER BOX

Honey Vinegar and Cider.

In the BEE JOURNAL, page 143, Mr. W. Z. Hutchinson gives us Mr. Bingham's plan for making honey vinegar, which he says was good. We made some last fall from the washings of vessels, after extracting. The honey was first-class, smartweed honey, but the vinegar had a sickening taste about it, and the only way we could use it was to mix it with sorghum vinegar, the kind we were using. Does honey vinegar usually have such a taste? JOSEPH BEATH.

Corning, Iowa.

[The honey vinegar we have made has not only been vinegar of the best kind, but it has also, while becoming vinegar, always been a palatable substitute for cider, and not distinguishable from it. It usually requires a year to mature so as to be a "tip top" article, and if very sweet, more time will be required, and better vinegar obtained. Mr. Beath may not have made his sufficiently sweet.—T. F. BINGHAM.]

My Valentine.

The past season was too wet for obtaining much honey. My bees did moderately well. I commenced the last season with 7 colonies, spring count, and increased to 13, and all are doing well, except 2 very late swarms, which are weak. I winter them on the summer stands. All but 1 are in box hives; that one hive is my own make, and the bees in it are doing better than any of the others, and I intend to transfer all the others, in the spring, into Langstroth hives, and would you use the old comb or foundation? What is the best time and plan of doing it? I send you a sample of my bees; are they the German or black bees, or are they hybrids? They show the yellow bands pretty plainly. My valentine was a swarm of bees. My wife being sick, leaving me to do all the house work as well as out-door work, confining me closely to the house, causing me to notice my bees more particularly. Two late swarms were weak, and I fed them syrup made from coffee A sugar, and yesterday, being very warm, I discovered a swarm of bees about 75 yards away, coming toward the house; they passed over it a little distance, and whirling round and round, came down, and tried to enter four or five hives; finally entered one having a weak colony. I have been feeding them since, and they seem very quiet and well satisfied. Where did they come from? And why did they come in such a manner? I never saw such a winter as this, with incessant floods; even the little creeks overflowed their banks, and the Ohio river was never known so high; it was almost from

hill to hill, sweeping corn and hay stacks off by wholesale; making almost a clean sweep. Now, the weather is sultry; the thermometer stood at 70° at 7 o'clock this morning, and at 80° at noon. Hot or cold I welcome the BEE JOURNAL; it is a weekly treat. I would be lost without it.

FRANK B. RIFE.

Malaby, O., Feb. 15, 1883.

[The bees sent are hybrids. We have already published several good plans of transferring, and will give several more before the time to do it arrives, which should be during fruit bloom. We cannot say where the bees came from, but they left some place that was distasteful to them or unfit for their longer abode, and sought and found some better place.—ED.]

What harvest follows a severe winter?

There is more mortality amongst bees, in this locality, than there were two years ago. One large apiarist, in this town, is losing very heavily, and losses are the rule. Many did not have fall pasturage, and had to be fed for winter stores; there was not much surplus last summer. Mr. Doolittle says the largest surplus, in this State, has followed severe winters; that has not been the case here, as a rule. 1868, 1870, 1874, 1876, 1878 and 1880 here were good seasons, while 1869, 1871, 1873, 1875, 1877, 1879 and 1881 were not so good, all following hard winters. The winters previous to the first named were mild with the exception of 1867 and the winter of 1870-71. The seasons of 1872 and 1882 were failures here. My average amount of extracted honey, per colony for 12 years, is 75 lbs. W. H. S. GROUT.

Kennedy, N. Y., March 30, 1883.

200 Lbs. of Wax from 70 Colonies.

In the BEE JOURNAL for Feb. 28, page 121, Mr. N. B. Tindall wishes for more light as to how I obtained 200 lbs. of wax from 70 colonies of bees, spring count. In my report I did not state that about $\frac{2}{3}$ of my bees were in odd sizes of frames, some of which I transferred on Mr. Heddon's plan, rendering up all of the old combs; those old combs and the cappings from 9,000 lbs. of extracted honey, is the way I obtained my 200 lbs. of wax. I should have stated in my report that had my bees all been in Langstroth hives, my report would have been much larger. I think another season will see all of my bees in standard Langstroth hives; then do not be astonished at any report I make. Last year I had one continuous and heavy flow of honey from June 7, until Sept. 15, and after I had finished extracting on Sept. 20, they filled their hives, both lower and upper stories; consequently they are very strong now. I will probably give my method of making vinegar in my next, which would be hard to beat.

W. G. McLENDON.

Lake Village, Ark., March 29, 1883.

Hard Winter in Canada.

This has been a very hard winter on bees; I think fully one-half the bees around here are gone. They have been confined 130 days, and are now very uneasy, and many suffering from dysentery. We have about 4 feet of snow on the ground yet, and it is freezing hard to-night.

GEO. GARLICK.

Warsaw, Ont., March 28, 1883.

Corrections.

Please make the following corrections in my article on page 166 of the BEE JOURNAL, and oblige: "The cap, which should contain about 1,000 cubic inches," should read, 7,000 cubic inches. The cap, or surplus department of all my hives, is large, and I do not think the case and cover together should contain less than 4,000 cubic inches to winter well. Also, the sentence, "but the bees seemed too warm, and *are* flying out, which, if they did much too often," should read, but the bees seemed too warm, and on flying out, which they did much too often. DR. G. L. TINKER.

New Philadelphia, O., Mar. 29, 1883.

[The figures 1 and 7, in writing, are made quite similarly, and there the 7 is blotted and indistinct. It occurs in the eighth line of the second paragraph in the second column on page 166. The other errors in the 12th and 13th lines from the bottom, were caused by carelessness in the compositor.—ED.]

Cheap Power for Saws.

As I have seen some inquiry, of late, in regard to a cheap power for running saws for hive making, I thought I would mention that the Buckeye mowing machine is about the best; for one that is rather "played out" can be bought for from \$2 to \$5. To use it, tip the machine up on one wheel, brace it up, and by digging a hole in the ground the size of the wheel and letting it down so that the tumbling rod can be attached about level with the ground, and run it out any length desired, to attach a pulley wheel. To attach to it, take the tongue of the machine to fasten to the top wheel, and hitch a horse at the end to go around in a circle. This makes a good power as well as a cheap one. I wintered 25 colonies on the summer stands, with chaff inside the hive, and lost only one; the rest are in fine condition.

DR. J. S. McALLISTER.

Columbus, Neb.

Wintered Successfully.

I wish to record the fact that I have wintered bees, for two winters, on sections, 8 inches square, two in a frame, wintered on from 4 to 7 frames in each hive, with the most perfect success. I arranged the sections, with their contents of honey and pollen, to suit myself. These frames are about the size of the Langstroth, and hang the long way up and down; thus holding one section above another, and are

movable at will. The hives that holds these frames are chaff hives, and are protected in the usual manner, except that the entrance is nearly at the top of the frames, which is an important point; it lets out all dampness, and lets in the bees at a point where it is warm. These frames can be handled in warm weather about as easily as the Langstroth, and bees will work in boxes as well as any other hive.

JOHN L. DAVIS.

Holt, Mich.

Queenless Colonies.

Please inform me, through the JOURNAL, the best method of treating queenless colonies in the spring.

Shirley, Ont. M. STONEHOUSE.

[Either give each queenless colony a fertile queen, or a frame of eggs and brood from which to rear one, early in the spring. The fertile queen is safest and best. Later, when drones are reared, the frame of eggs and brood will do. Or, if you have a weak colony, with a fertile queen, unite the queenless colony with it.—Ed.]

Meeting of Bee-Keepers.

I put 83 colonies in winter quarters, on the summer stands, and left the cloth on the frames. I put a box over the hive, packed around with hay, and covered all with a good roof. Those packed thus came out strong on April 2, as they were when put there, as far as I could see. Some, left without any outside packing, carried out from a half to a pint of bees, after the cold spell. The bee men of Joplin and adjoining country meet at Joplin, May 5, 1883, for the purpose of organizing a Society for the advancement of bee-culture, and to establish a uniform price for the products of the apiary. All who are in anyway interested in apiculture, are invited to meet with us at that time and place. The Society will hereafter meet at such times and places as may be determined.

DR. J. T. BRUTON.

Joplin, Mo., April 3, 1883.

When to take Bees out of Cellars.

When I read reports like the one in the BEE JOURNAL from J. E. Hastings', Carlisle, Iowa, page 170 (and others similar to it which the reader will call to mind), I must say I am puzzled to understand them. If I should say to the Dairyman's Association I put 20 cows into the stable on Nov. 1 and on March 1 or 16, I turned them to pasture all in good condition, what would northern farmers think of me? I can easily guess that they would say, to themselves: "If he has any left May 1 they will be a slim lot indeed, especially in such a season as this." It has been a howling month; the ground is frozen solid yet, with but very few days that bees can fly. I infer that it is very similar in Mr. Hastings' vicinity. In short, I would like to know, as long as the bees are in fine condition in their winter quarters, and considering the state of the weather, why not leave them

there, even until May 1 or 15, if there should be nothing for them to do outside until that time. I think the opinion prevails among bee-keepers that cellar-wintered bees are liable to dwindle badly when set outside, in fairly good weather! I would like to see Mr. Hastings' report on May 1. I expect that he will wish that his bees had remained in the cellar and cave another 4 weeks. I packed 25 colonies in October in clover chaff, bottom, top, and sides; all are living, but 1, which was dead Feb. 15.

P. F. TWITCHELL.

Andover, O., April 2, 1883.

Large Increase and Honey Crop.

I have no doubt but what there is a difference in locality for honey; the best we can do here is the average of 30 lbs. of honey to a colony. I would be glad to have large increase and large honey crop, as Mr. Moss says he had (from 16 colonies and 3 nucleus, 3,600 lbs. of honey, and 52 increase, and all that a family of ten could use for a year); that stumps the world. I am 76 years old, but never witnessed such a thing, as the above, in my life.

WILLIAM ROBERTS.

Vaughansville, O., April 3, 1883.

Convention Notices.

☞ The Mahoning Valley bee-keepers will hold their 13th meeting in the Town Hall, at Berlin Centre, Ohio, on May 5. All bee-keepers, and the public in general, are invited to attend. Do not forget to bring your wives, children, and a well-filled lunch basket. We expect a grand meeting.

L. CARSON, Pres.

H. A. SIMON, Sec. pro tem.

☞ The Iowa Central Bee-Keepers' Association will hold their semi-annual meeting at Winterset, Iowa, on Friday, May 11, 1883. All interested in anything pertaining to bee-culture are invited to attend, and bring anything that will be of interest to the bee fraternity.

J. E. PRYOR, Sec.

A. J. ADKISON, Pres.

☞ The semi-annual meeting of the Western Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to bee-keepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, Sec.

Kansas City, Mo.

J. A. NELSON, Pres. Wyandotte, Kas.

☞ The spring meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, Sec.

☞ Quite a number of the leading bee-keepers of Missouri and Kansas met at the Court House, in Independence, Mo., December 23, 1882, and organized a bee-keepers' convention, which was named the "Western Bee-Keepers' Association," by electing the following officers for the ensuing year: Jas. A. Nelson, of Wyandotte, Kans., President; L. W. Baldwin, of Independence, Mo., Vice-President; S. W. Salisbury, Kansas City, Mo., Treasurer. The Association passed a resolution to invite all bee-keepers within a convenient distance, to meet with us at our next meeting and lend us their councils. Adjourned, to meet again at Independence, on the last Saturday in April next, at 10 o'clock, a. m. J. D. Meador, P. Baldwin, C. M. Crandall, Committee.

☞ The Central Michigan Bee-Keepers' Association holds its spring convention at Lansing, in the State Capitol building, on Tuesday, April 17, 1883, 9 a. m. Programme: President's address; Essays: Prof. A. J. Cook, on Wintering Bees; S. C. Perry, on Chaff Hives; C. Case, on Comb Honey; O. S. Smith, on the Best Bee; A. D. Benham, on Extracted Honey; Mr. Harper, on Queen-Rearing; Mr. Waldo, on Best Method of Wintering Out of Doors, in Single-Walled Hives; E. N. Wood, on Sections; and E. Greenaway, on Comb Foundation. All bee-keepers are invited to attend or send essays, papers, implements or anything of interest to the fraternity. A full attendance is requested.

E. N. WOOD, Sec.

North Lansing, Mich.

☞ The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, Sec.

Coopersville, Mich.

☞ The Texas State Bee-Keepers' Association will hold its Fifth Annual Convention at McKinney, Collin Co., on Tuesday and Wednesday, April 17th and 18th, 1883; at the residence of Hon. W. H. Andrews.

WM. R. HOWARD, Sec.

Kingston, Texas.

☞ The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

☞ The Southeastern Michigan Bee-Keepers' Association will hold their next meeting at Adrian, Mich., April 18, 1883. All are invited. Reduced rates at hotel.

H. D. CUTTING, Pres.
Clinton, Mich.

H. C. MARKHAM, Sec.

Ann Arbor, Mich.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Sections, Honey Board, Etc.

Will Mr. Heddon please answer the following questions through the BEE JOURNAL? And oblige a reader of all your articles, and one that thinks a great deal of them.

1. In using one-pound sections, is it best to use one or two tiers, in surplus-chamber, same as in brood-chamber?

2. What is the best time and way to fasten brood comb from larger frames into the Langstroth frame?

3. Please describe the honey board that you use between the brood and surplus-chamber? A. H. GIVEN.
Elgin, Ill., April 3, 1883.

[1. Whether I used a case or brood frame super, I should never use either more than one tier high.

2. In these days of comb perfection, I should never transfer combs unless they were all worker, perfectly straight, and large enough to completely fill the frames, and then if you have a flat top bar, nothing is necessary if you cut and press in the comb properly. Thorns put through bradded holes, in the top bar, are good to secure the combs till the bees make them fast.

3. My honey board is described on page 201, Weekly BEE JOURNAL, 1882.—JAMES HEDDON.]

Preventing After-Swarms.

I liked your article very much on "Preventing After-Swarms." I understand from it that you did not give the old colony a laying queen immediately, forcing them. Is it not advisable to do so? DWIGHT FURNESS.
Furnessville, Ind.

[In back numbers of the periodicals and in conventions, I have always contended against the plan of rearing and fertilizing queens to be used for the queenless part of a divide, or in natural swarming. A cessation from egg laying is just fitted to the condition of the mother colony at the time when the natural division does, or artificial division should occur. There is no better place in which to hatch cells than this old colony; none any where near as cheap. Do not let us get ahead of the old farmer any faster than we will pay. Let our advancements be real. Mr. Doolittle's article on page 174 of last issue contains most of the arguments that I have used. I differ with him regarding the point of the introduction of the new queen to the old colony, producing further

swarming. It will not, here, or any where else, that I know of, for nothing tends more to prevent the swarming impulse than the introduction of a young queen. The real objections are that it is a useless expense, of time, for the cessation of laying is just to our advantage at that season of the year. This is another point on which the "advanced" ones used to "churn" me upon.—JAMES HEDDON.]

Chocolate for Pollen.

As a suggestion, what do you think of sweet chocolate as a substitute for pollen? My bees are highly pleased with it. WM. D. FRENCH.
Grand Rapids, Mich.

[I have never heard of chocolate as a substitute for pollen before. You must find out by experimenting. Here in my location, and I believe the same is true in yours, there is nothing gained in early breeding. I am satisfied that all the sacks of flour I ever fed were worse than wasted.—JAMES HEDDON.]

Keeping Honey in Summer.

How can I keep extracted honey from souring in summer; and also comb honey from candying?

N. S. DEAN.
Hooper's Valley, N. Y.

[Do not extract your honey till it is capped over, and there is no danger of its souring. If you do extract it in a thinner state, store it in 1 gallon stone jars, piled 8 or 10 high, with sticks between them, to allow a circulation of air across the top surface of the honey. It can thus be stored in a very small compass, in proportion to quantity. The room containing it should be dry and airy. To keep comb honey from candying, have all capped before removing from the hives, and keep it in an airy and warm room. Keep warm in cool weather.—JAMES HEDDON.]

On page 183, center of middle column, answer 4, read: "A majority seem to think so, though minorities," etc. No matter where the error was made, let us have it as near correct as possible. I have to write on the run. [It was not so written.—ED.] I must refuse to answer questions not pertaining to business, except through the Question Departments I have agreed to. 1. Because I cannot get the time to do it. 2. Answers in the Departments save an endless repetition of the same questions. If they are repeated, I can refer to former answers.—JAMES HEDDON.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., April 3, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESEWAX—None in the market.

A. L. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@18c. on arrival.

BEESEWAX—Comes in slowly and brings 20@30c per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15@16c. for white, and dark undrained. Extracted, very little trade is being done in it. 7@9c. is about the market.

BEESEWAX—3@4@30c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Buyers are readily obtained for choice comb or extracted at full figures, but off quantities meet with slow sale.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9c.; dark and candied, 5@7@9c.

BEESEWAX—We quote 30@33c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16.—some inferior sold at 10c.; strained at 6@7c., extracted at 7@8@9c., lots in small packages more. BEESEWAX—Scarce and wanted at 33@34c. W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18@19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17@18c. Extracted very dull at 9@11c.

BEESEWAX—None in market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels. BEESEWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts each, or \$8 per 100.

We have a few copies of our pamphlet entitled "*Bee Culture*" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The *Bonheur des Dames*; or, *The Shop Girls of Paris*.—Emile Zola's new novel, just published by T. B. Peterson & Brothers, Philadelphia, is his greatest, most finished, and most absorbing romance. It opens up an entirely new field in fiction, and will be seized upon with avidity by countless hosts of readers. In nothing Zola has written is his vivid naturalism so pronounced. The scene is laid in the "Bonheur des Dames" dry goods store, an immense Parisian establishment, employing a whole army of girls and men. Zola pictures this store from its modest beginning, showing how it grew day by day, ruining rival houses, and gradually monopolized all the business of a vast quarter of Paris. The daily life of the shop-girls and salesmen, their trials, troubles, temptations and triumphs are depicted in the most graphic and realistic fashion. The heroine is one of the shop-girls. She goes through the same experience as the others, but differs from the majority of Zola's heroines in preferring purity to dissipation and its gilded allurements. She is, in short, a good girl; pure, guileless and innocent. Snares are set for her, but her very purity enables her to escape them all and come out unscathed from many a trying ordeal. She ultimately reaches a suitable social position, attaining fortune and happiness. Price 75 cts.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bees for Sale!

200 or 300 colonies of Italian bees, in Langstroth hives, in good condition. Price: Single colony, \$5.50; ten or more, \$6.00 per colony. Hybrids, 50 cents less. I will guarantee safe arrival.

C. GRIMM,
Jefferson, Wis.

JUST OUT!

New circular and price of Bees and Queens. Also, STENCILS for bee-keepers' use.
JOS. M. BROOKS,
Columbus, Ind.

FOR SALE—ITALIAN BEES.

Five to seven dollars per colony.

E. A. GASTMAN,
Decatur, Ill.

COMB FOUNDATION.

Owing to the scarcity of beeswax, the prices of comb foundation will hereafter be as follows:

	Dunham.	Thin.	Extra Thin.
10 lbs. or less.	55c.	65c.	72c.
25 " "	54	64	71
50 " "	53	63	70
100 " "	52	62	69

Cheap! Cheaper!! Cheapest!!!

300 COLONIES OF BEES

for sale, in movable frame hives. Also, Queens, Nuclei, Bees by the pound, Hives, Sections, Smokers, Seeds for Honey Plants, and everything a live bee-keeper needs. Send for circular and price list to

FLANAGAN & ILLINSKI,

Box 819, Belleville, St. Clair co., Ill.

(Proprietors of Rose Hill, Cahokia, Falling Springs and Lake Apiaries. 1A11y)

What Shall I Feed my Bees?

To stimulate early breeding and insure **STRONG COLONIES** is the all important point. Cotton-seed-meal which contains far more nitrogenous material than any other vegetable product except pollen. See instructive article by Arthur Todd in the BEE JOURNAL, page 162. I can furnish a prime article at 3¢ per lb., or 3¢ if more than 50 lbs. are ordered. GEO. E. BOGGS, Morgan, Ky. 1A11t

Vandervort Foundation Mill.

6 Inch, Price, \$25.00.

It makes the finest extra thin Foundation for comb honey. For Sale by

ALFRED H. NEWMAN,

923 West Madison St.,

CHICAGO, ILLINOIS.

NOTICE.

You have bought me all out of my prepared stock of hives and shipping crates in the flat. I can't make any more, and fill other orders promptly, and perform my desk labor. I can't trust any one else to do it. Will you please scratch from my list, "HIVES AND SHIPPING CRATES IN THE FLAT?" I will furnish hives made up, honey boards, brood frames and sections in the flat, and in fact all other goods advertised in my circular, the same as before.

EDITOR AND PROPRIETOR.

New Book on Queen Rearing.

Mr. Henry Alley's new book on Queen Rearing is received, and we are very well pleased, not only with its contents, but also with its typography and binding. It is a handsome octavo of 200 pages, and contains 20 illustrations.

This is one of the subjects upon which "more light" has been demanded for some time past, by progressive apiculture, and we are glad to welcome this work of Mr. Alley on the subject, because he is a successful and experienced queen rearer, and also because he gives details of the methods he now practices, after many experiments covering a period of 22 years, during which time he has, perhaps, produced and reared more queens than any other breeder.

Of course, there are many things stated in the book which we cannot endorse, and also much that we think needs confirmation—still it is a valuable addition to the sparse literature on "Queen Rearing" now extant. Considerable of the repetition will no doubt be eliminated from the next edition.

In the Preface, Mr. Alley remarks as follows:

I need not state that this work was not intended as a literary effort, as indeed I make no pretensions in this respect. I have endeavored to present to my readers a work that will be beneficial and advantageous to them and have tried to avoid all that is superfluous or ambiguous, believing that plain, practical common sense is far preferable; and if it meets with general approval I shall rest content. I claim that my method of rearing queens is new and original, being the

results of my long experience in queen rearing and practical apiculture.

By the careful study of this work, and by putting into practice the directions herein given, one will experience no difficulty in rearing queens of a superior quality. Let it ever be our aim to rear *better* not *cheaper* queens.

We have waited long for the appearance of the work, but have lost nothing by the delay. Mr. Alley says: "The long delay in the publication of the Bee-Keepers' Handy Book, was unavoidable, and was caused mainly by the addition of nearly 75 pages to the work more than was originally intended. My readers will profit by this gain, which is a loss to me of over \$100.00." Now that it has been issued, we can cheerfully forget the delay, and attribute it to the author's inexperience in the business of publishing.

In his Introduction the author remarks as follows:

The present and future interests of apiculture demand a more thorough and practical method of rearing queens, and I shall endeavor in this work to give my readers such information as shall tend to give a new impetus to this branch of bee-keeping, and also aid, if possible, in doing away with the cheap and worthless queens produced under the lamp nursery system; and to offer to the bee-keeping public, for their careful consideration and adoption, a thorough, practical and scientific method of queen-rearing, which is the result of many long years of practical experience, and much hard study.

In order to become a successful instructor one must first attain a complete knowledge of the subject to be taught, and unless it has been thoroughly and fully mastered in all its details, failures only can result.

In presenting this work to the bee-keeping fraternity, I do not wish to assume the position of teacher, but rather to place before its readers in as plain and practical a manner as possible my method of rearing queens, leaving to their judgment the careful study, and candid criticism of its contents, feeling assured of a favorable decision regarding its merits and value; knowing that if its instructions are carefully studied in all their details, and put to a practical test, the result will be successful. By careful

attention to all the rules laid down herein, I hope better queens will be produced, a matter of great importance to the bee-keeper whether he keeps bees for pleasure or profit; and of vastly more importance to the bee-master who follows it as a vocation and depends upon the same for a living.

He then enters into details of the *modus operandi*, by which these "better queens" are produced, and describes his methods and management. A chapter is also devoted to each of the following subjects: Transferring Bees; Spring and Fall Feeding; Wintering Bees; Keeping Bees for Pleasure and Profit, and General Remarks, which includes a multitude of subjects.

Two essays are also incorporated into the work, the first being on "Management of the Apiary; or, the Production and Marketing of Honey," by G. W. House; the other is on "The New Races of Bees," by S. M. Locke. Both of these are very interesting and instructive.

This new work should be in the hands of every practical apiarist, and is worth many times its cost to any one having the care and management of bees. It can be obtained of the author, at Wenham, Mass., or at this office.

☞ Quite a number of the new subscribers, who have begun to take the JOURNAL this month, ask if we can supply the numbers from Jan. 1, 1883. We would say that we can supply a few more sets, and if any want them they must be sent for *soon*, or they cannot be obtained. We can supply no more numbers of 1882. They are all gone.

☞ The 23d annual St. Louis Fair will be held Monday, Oct. 1, to Saturday, Oct. 6, 1883, both days inclusive.

☞ Articles for publication must be written on a separate piece of paper from items of business.

Glucose—A Scrap of History.

Mr. W. H. Graves, Duncan, Ill., has sent us the *Peoria Journal*, of Feb. 13, 1883, which contains some historic items of interest on the glucose industry which has been so detrimental to honey producers. It says:

One of the curiosities of trade in these latter days, is exhibited in the rise, meridian and decline of the glucose industry. Less than five years ago the general attention of the commercial world was directed to glucose. Beginning in Germany it was first manufactured from wheat. It was carefully made by experienced chemists, who personally superintended its manufacture through every stage. An excellent product was the result, which, being placed on the market, found a ready sale at prices which yielded immense profits.

It was not long before the process of manufacturing glucose was known in the United States. Works were erected in Buffalo, N. Y., at a time when this country was in the throes of a financial panic, and when everything in the shape of labor and material could be obtained at remarkably low figures. Immense factories were erected at a minimum cost, tons of machinery were procured for about the value of old iron, corn was away down among the thirties, and labor was begging for employment. Under all these favorable conditions, the glucose factories, that were first in the field, made vast sums of money. A profit of several hundred per cent. per month, on the original investment, was only a circumstance.

New uses for the manufactured article was discovered daily. Its first extensive use was in the manufacture of confectionery. Then it became an adulterant of molasses, for which hundreds of thousands of barrels were used annually. Solidified and placed on the market as grape sugar, it was used to mix with the lower grades of cane sugars. It crept into the pharmacist's laboratory, and there made itself generally useful in several ways. The brewer hailed it joyfully, and it found a temporary abiding place in his capacious vats before lubricating many a parched esophagus, in the shape of lager beer.

Then did glucose find favor with the capitalist. It had an almost universal demand; it could be made from corn, the cheapest of grain, and the process of its manufacture was as easy as eating cheese. All that was necessary was to soak the grain in water for so many hours, grind it between burrs while wet, run the slop into tubs to allow the starch to settle, drain off the water, dump the starch into another vat with sulphuric acid to convert it into sugar, neutralize the acid by adding marble dust, strain the product, boil it down to syrup in a vacuum at a low temperature, strain through bone charcoal, and finally through felt presses, and the syrup was ready for the barrel.

Thus amazed at the apparent simplicity of the process of manufacture,

and dazzled by the tangible profits on the investment, capitalists took kindly to the new industry, and glucose factories sprung up all over the country.

About the time that everything was in readiness for turning out glucose and coining money, the country began to recover from the effects of financial depression. The price of corn advanced from 30 cents to 80 cents, at which figure the manufacture of glucose ceased to be gratifyingly profitable. Higher wages were demanded and paid, and competition, which, by this time had grown sharp, lowered the market price for the finished goods. To add still further to increasing perplexities, it was found that the process of making glucose was not so simple as it seemed. An expert chemist, at a princely salary, was a necessary adjunct to every corn sugar works, and even then not one in ten of these alleged experts could turn out a pure article at a profitable figure. Other drawbacks arose. The factories were extremely liable to destruction by fire, necessitating high insurance rates; the cane sugar crop for a year or two was abundant, and consequently reduced in price, and a new process was discovered for making cheap sugar from sorghum.

All these forces have combined to give glucose a discolored optic. Two years ago the corn sugar factories in Peoria consumed 10,000 bushels of corn a day. Now but 2,000 bushels are used daily. One of the factories burned down, and was rebuilt with only one-third of its former capacity. The other factory has been closed for nearly six months, and now stands deserted. Of 20 glucose works in the United States that were running at full capacity a year ago, only six are running to-day, and five of them are running at reduced capacities. Fortunes, instead of being made, have been swallowed up in glucose slop. Hamlin, of Buffalo, and Chaffee, of Tippecanoe, Ind., are the only men who have made fortunes at the business, and they were the first in the field.

This is the history of the glucose industry; bright at its dawn, cloudy at its noonday, and gloomy in its night—mighty but ephemeral, so does it pass before us as one of the commercial curiosities of the nineteenth century.

Seasonable Hints.—The *Indiana Farmer* gives the following hints to beginners about handling bees:

Gentleness and firmness are necessary qualities in the handling of bees. Sudden jars and quick active motions should be avoided as much as possible. During a good honey flow there is little if any danger of being stung, with anything like fair treatment for the bees. With little honey coming in, they are much more liable to resist interference. By the judicious use of smoke they may be controlled with but little trouble, and while it is not necessary to resort to this under all circumstances, it is best to have the smoker ready so that it can be used if

the occasion requires it. The construction of hives, too, has much to do with the handling of bees. The frames should hang so that they may be taken out without first having to pry them loose, for there is nothing that will arouse their anger sooner, than the sudden snapping and breaking loose of a frame. Where the frames must be pried loose, one should be provided with a strong-bladed knife, or small screw driver; pry the frames loose, one at a time very gently, loosening all of them before removing any. In fact anything about a hive that must be pried loose should be manipulated carefully.

It is the instinct of the bees to fill themselves with honey when disturbed. Smoke seems to do this more effectually, with less danger of angering them, than anything else. But the smoke has no effect on the bees only as it causes them to fill with honey. This is the object of its use and it is beneficial in no other manner, unless it be simply to drive them out of the way. They seem to fear the smoke and offer less resistance to it, although, if given too much, it may make them very angry. Preparatory to opening a hive, smoke should be blown into the entrance, not too much at once; better two light applications at short intervals.

After the bees have had time to fill themselves, remove the cover, raise gently one corner of the cloth over the frames, or what ever they may be covered with. If they still show resistance, give a little smoke at this place, and with very few exceptions they will submit to anything in reason; but bear in mind, the mashing of a bee, the dropping of a comb, or accidents of like kind may cause them to strike for liberty or death.

Bee Notes for April.—The *American Agriculturist* gives the following on the results of the past winter among the bees:

Although bees should be set on the summer stands in April, even in the more Northern regions, still they should be closely covered with warm packing. For two years we have put into our cellar chaff hives and hives with single walls, all containing bees. These were set out at the same time. The bees in single hives were closely covered with a sack containing fine sawdust. This was so long that it not only covered the hives, but reached over at each end, and hugged the division-boards that confined the brood-chamber. So far as we could discover, the bees in these hives suffered no worse from "spring dwindling" than did those kept in chaff hives. If future experience sustains this point, then the argument that chaff hives are desirable, because they are safer in spring, is of no importance. The past severe winter will enlighten us on this subject. We shall be mistaken if it does not raise cellar wintering to a premium. Such long confinement, with severe cold, is very hard on bees. If chaff hives prove equal to the situation, this winter, then their value is assured.

For the American Bee Journal.

Rearing Queens—Nuclei System.

W. Z. HUTCHINSON.

I have learned that nothing is gained by commencing operations very early in the season. Colonies are weakened, brood is chilled, and queens do not lay until they are two or three weeks old; in fact, there are only unpleasant features connected with commencing before warm weather has really come to stay; which, in this latitude, is usually about the 10th or 15th of May.

My first step is to put a nice, clean, light-colored worker comb in the centre of the colony, having the queen from which I wish to breed. In three or four days I generally find this comb filled with eggs, the oldest of which are beginning to hatch into larvae. I now remove the queen and all the brood from some strong colony, shaking the bees from the brood combs back into the hives, and dividing the brood among the weakest colonies. The queen is either sold or given to a nucleus prepared expressly for her. The comb of eggs and larvae from the choice queen is now given to the queenless and "broodless" colony. I usually cut a few holes in the comb, just where the eggs are beginning to hatch, as it gives the bees better opportunities for building queen-cells. The date that the cells are to be removed, is marked upon the top-bar of the frame, and this date is also written upon a Record Board, fastened up in a conspicuous place in the shop. This board is examined each day, thus no batches of queen-cells are forgotten and neglected until some of the queens hatch and destroy the whole lot of cells. When a batch of queen-cells are taken from a hive, the date of that batch is scratched from the board, and when a new batch is started, the date that they must be removed is written upon the board. I have found nine days about the right time for leaving a comb of eggs and just-hatched larvae in a queenless colony; the brood is then all sealed over, and the queen-cells well ripened, but no queens will hatch in that length of time. I never shake the bees from a comb upon which are queen-cells, as, if the queens are not far advanced, the sudden jar will often dislodge them from their bed in the royal jelly, and they fall to the lower end of the cell where they perish, while, if they are farther advanced, but not fully developed and hardened, the result may be queens with crippled wings or legs. I place one edge of the comb upon the ground near the entrance, coax off as many bees as I can with the smoker, and then brush off the remainder with a feather. After removing the comb of eggs from the colony having the choice queen, its place is filled with another nice comb

or sheet of foundation; and in three or four days this will be filled with eggs, and can be given to another queenless colony. With 125 nuclei I have found it necessary to start a lot of queen-cells every day. I seldom allow a colony to build more than two lots of queen-cells, when I give it a laying queen.

A day or two before I expect the first lot of cells to hatch, I start as many nuclei as there are cells. Early in the season I seldom start more than one nucleus from each colony, and I do this by taking three combs with the adhering bees and placing them in a nucleus hive, taking care, of course, not to remove the old queen. At least one comb should contain brood, and it is better that a little of it should be unsealed. As the weather becomes warmer, more nuclei are formed by taking combs with the adhering bees from these three-frame nuclei, leaving only two combs in a nucleus. More nuclei are also formed by taking more combs with the adhering bees from the full colonies. If a colony can spare only one comb, it can be taken and put with a comb from another colony, and thus form a nucleus. I have had no trouble from bees quarreling when they were united or mixed up.

I consider it important to always have on hand a good stock of queen-cells. A breeder cannot rear queens at a profit if he allows some of his nuclei to remain queenless several days for lack of queen-cells.

When honey is coming in plentifully, I prefer to put a laying queen upon the combs of the nucleus at the same time that I remove the laying queen, but when there is a scarcity of honey, this plan does not seem to work so well, unless the bees are fed, as some of the young queens are killed by the bees. I have frequently introduced young queens that were three days old; and one breeder, with whom I talked last winter, says that he has often made a practice of keeping virgin queens until they were five or six days old before introducing them, they would then often become fertilized the next day after they were introduced, and five days' time would thus be gained. Before introducing, these young queens were kept confined, each queen by itself, but accompanied by a few workers against the side of a comb of honey kept hanging in the lamp nursery. The cages used to confine the queens were similar to a cover of a tin pepper box, only the tops were wire cloth; in fact, they were the cover to some discarded "Harris mailing cages." A queen and five or six workers were placed under a cover, then give the cover a turning motion, combined with a slight pressure against the surface of the comb of honey, which caused the sides to penetrate the comb sufficiently to keep the cage in place. To introduce one of these queens the bees were shaken from the combs of a nucleus upon the ground, near the entrance, the queen put into the nucleus, the nucleus closed except the entrance, and then the bees allowed to run back in. He seldom lost a queen

in introducing them, and had been unable to discover that this practice injured the queen in any respect.

One more point I consider important, and that is that no nucleus shall remain a single day without unsealed brood. Attention to this matter saves a world of trouble, and largely increases the profits.

Rogersville, Mich.

For the American Bee Journal.

Ventilation of Bees.

S. CORNELL.

I agree with Dr. Tinker in the opinion that the only really troublesome factor with which bee-keepers have now to contend, is the best mode of winter ventilation. Sometime ago I completed a sort of digest of articles on wintering, and of everything said on the subject as reported in the proceedings of bee-keepers' conventions. This comprised all I could find relating to wintering in 36 volumes of the current periodicals, and in the standard works on bee-culture. The items, thus gleaned, were then classified and arranged under such headings as Cause of Dysentery, Cure of Dysentery, The Pollen Question, Where Wintered, Protection, Condition of Cellar, Temperature, Ventilation of Repository, Stores, Upward Ventilation, Lower Ventilation, Side Ventilation, No Ventilation, Space Below Combs, Results, etc. From reading the apparently contradictory theories and plans for wintering, scattered through the bee papers, one is often at a loss to know which method to adopt. On this subject, a prominent bee-keeper writes as follows: "The reports about wintering are so conflicting that they point to nothing definite, and I confess that I am wholly ignorant of the whole matter." But when the evidence is arranged under such headings as the above, and carefully examined, and the degree of intelligence and success of the observers are taken into account, I am quite sure my friend would agree with me that the weight of evidence is overwhelmingly in favor of the opinion that the removal of vitiated air as fast as it is produced, and the substitution of fresh air in the place of the foul air so removed, is the plan which has proven to be most successful, and that to the want of this change of air can be traced an exceedingly large proportion of the cases of disaster.

The principles constituting the science of ventilation are always the same, whether considered with respect to hives containing bees, the cellar containing the hives, or the apartments above occupied by their owner. Let us see if what is known regarding those principles cannot be made to assist in providing proper ventilation for our bees.

We are told "The necessity for change of air in inhabited spaces is rendered evident by considering the sources of contamination. They are: a. The production of carbonic acid gas by respiration. b. The increased

moisture from the same source, and from exhalations from the body. c. Heat thrown off by the occupants."

The object of ventilation, therefore, is to remove the air thus vitiated, and so substitute pure air, of the proper temperature and humidity in its stead. We are further told, "Every person is surrounded by an envelope of vitiated air, and the thickness of this envelope is dependent upon the direction and velocity of the air past the person." This is equally true when applied to a cluster of bees instead of a person. The extent of the contamination is sometimes determined by the increased quantity of carbonic acid, and sometimes by the increased quantity of aqueous vapor found in the air. An eminent authority says: "To measure the additional amount of moisture at any point is, therefore, to determine the foulness of the air at the same point." It has been calculated that the consumption of 30 pounds of honey, by a colony of bees, will produce 140 barrels of steam, or about a barrel per day while they are in winter quarters. Suppose they only consume 10 pounds, each colony will evolve a barrel of steam every three days, a quantity so great as to make it imperative that it be ventilated out of the hive, and hustled up the chimney with as little delay as possible.

In a former article, page 728, BEE JOURNAL for 1882, I pointed out that the combustion of the saccharine part of the food produces only carbonic acid gas and water as excreta evolved by respiration and evaporation, and that the surrounding air must be in a condition to take these up as fast as produced, to keep the bees healthy. The necessity for evaporation, and the conditions under which it can be carried on, may be gathered from the following statements as regards ourselves, and they have even greater force when applied to the bees.

"For health the body must evaporate a quantity of water within certain limits. The amount evaporated, is influenced by the hygrometric condition of the air." * * * "It does not hurt a young, strong, healthy person so much to draw the water out of him too rapidly, or too sluggishly, as it does an old, feeble or sick person, but the health of the most vigorous man is gradually undermined by any extended persistence in living in air, which has either a great excess or deficiency of moisture; and one of the greatest difficulties about it is, that in nine cases out of ten, he does not know why his health has failed." In the winter of 1880-81, we had nearly four months of excessive moisture in the air, without any break or let up to it. If there had been spells during which the air was dry, so that the bees could get dried out and take a fresh start, it is probable they would not have suffered so much. It seems to be the long continued excess of moisture that is most injurious.

The atmosphere is the great absorbent upon which we all have to depend. As remarked by the president of our Ontario convention, last fall, the so-called mechanical absorbents are

merely transmitters of moisture from the bees to the surrounding air. When intelligently handled, the atmosphere is the most efficient as well as the cheapest absorbent bee-keepers can employ. Let us examine this matter a little. Air at zero is saturated by a very small quantity of vapor, and can then absorb no more. On the 12th of December last, we had a silver frost, the temperature being down to 8° at 7 a. m. The women complained that the clothes put out on the line, would not dry as usual. The reason was, because the air was already saturated, and could not evaporate water from anything.— Suppose we take a sponge saturated with water and compress it. While compressed it may hold, say an ounce of water, but it will still be fully saturated, and can take up no more. But remove the pressure, and presently it is increased in bulk, and, although, it still contains the ounce of water, it is now thirsty for more, and is capable of absorbing several ounces in addition. At zero, 545 grains of watery vapor will saturate a cubic foot. Raise the temperature to 32°, and it will become so thirsty for vapor that it will require 2,126 grains to saturate a cubic foot, and at 70° its greed for moisture will be so increased that it will require almost 8 grains per cubic foot to produce saturation. Heating air does not dry it in the sense of taking moisture from it; it only renders it greedier for more.

I am not forgetting the fact that, although the air in the hive may be very damp yet, being of lower temperature, as it permeates the cluster and is breathed by the bees, its temperature is raised, and is in this way rendered capable of taking up the water from the body of the bee. The extent of this increased capacity will depend upon the heat of the cluster. Prof. Newport says this is sometimes as low as 30°, but I have found it to be between 60° and 70° with the surrounding air at 40°. It is doubtless owing to this fact that bees are able to live as long as they do in badly ventilated hives. But I confidently make this statement, that when vapor is produced by the cluster of bees faster than it escapes from the hive by ventilation and diffusion, or faster than it is diluted by the quantity of air contained in the hive, it is only a question of time till the bees will have to succumb to the effects of moisture and pernicious gasses, and the length of that time will depend upon the strength of the colony, the readiness with which diffusion takes place through the material surrounding the bees, the quantity of air contained in the hive to dilute the vapor and gasses, the extent of the openings for ventilation, and the relative humidity of the air entering the hive from without. People often wonder why some colonies die, while others alongside, apparently in the same condition in the fall, come through all right. It is hardly possible to find colonies exactly equal in all the above particulars. A closer examination would doubtless show differences in the conditions sufficient to account

for the different results. But we are told that the humidity of the external atmosphere has no relation to bee mortality. No engineer of eminence will be found to make the statement that the relative humidity of the external air has no relation to good ventilation. As a matter of fact, it is a factor always taken into account. In laying stress on this element in the case, I do not stand alone amongst the bee-keepers, nor can I claim priority in bringing it forward. On page 727 of the BEE JOURNAL for 1882, Mr. F. Della Torre says: "When the atmosphere outside is damp, that in the hive is more so, for it has the large amount additional from the breath of the bees added to it." On page 70 of *Gleanings* for 1882, Mr. George Grimm calls attention to this as an element of importance which has generally been overlooked. He claims that the natural moisture contained in the air affects the honey, the bee-bread, and the bees themselves, and frequently leads to disease. Mr. James Heddon says that, in his climate, "out-doors rivals the poorest cellars for damp atmosphere; in fact, it far exceeds them." If we knew exactly how damp it is, it might possibly furnish a clue in discovering the reason why dysentery "gets there" pretty badly at times in spite of his skill as a bee-keeper. One of the largest bee-keepers on the continent gave it as his opinion recently, that the air in the neighborhood of Mt. Healthy, O., is comparatively dry, and that this is one reason why Mr. J. S. Hill has been so uniformly successful in wintering, but, as in Mr. Heddon's case, we have no reliable data on the matter.

The following cases will serve to illustrate the application of the foregoing principles, and possibly be of service in helping to save some of the bees now suffering from dysentery.

On page 346, of the BEE JOURNAL for 1881, Mr. G. W. Zimmerman says, that on one occasion, when bees were dying from dysentery, his 65 colonies were uneasy, very wet and distended. He heated a room with a stove, removed the quilts and entrance blocks. "All the bees that were affected with dysentery came out over the hives. I did this twice from evening till midnight, keeping the room dark. They all dried off and clustered quickly back in their hives again. They had discharged their feces going out and coming back. The result was, I saved all but two queens.

In the same volume, page 129, Mr. S. Valentine describes how he cured several colonies of dysentery by making an opening 2½ x 4 inches, covered with wire cloth directly over the cushion. In a few days he found that those that were almost helpless had become dry and bright.

On page 258 of *Gleanings* for 1876, Rev. M. Mahin, D. D., describes a case in which he found the whole interior of his hives dripping wet, and the bees dying through lack of ventilation. He removed the honey-boards, and replaced them with pieces of carpet. After a few days he found the hives dry, and the bees healthy.

They both wintered and springed well.

Mr. M. H. Snyder tells, on page 583 of *Gleanings* for 1881, how he saved his bees, which were dying of dysentery, by raising the hives above the bottom board and loosening the enamelled cloth with which they were covered. A few days after, all were dry and in good condition.

On page 593, of the same volume, Mr. G. W. Stitts tells how he cured two colonies half-dead with dysentery, by heating the hives and packing hot cushions and hot bricks over them, and by repeating this once a week for three weeks, they were effectually cured.

On page 452, of the same volume, Dr. Jesse Oren relates how he succeeded in wintering bees in box-hives by inverting them and tiering them up in the cellar; how, he also succeeded with Langstroth hives in the same way, leaving the holes in the honey-board open, and keeping them apart by strips of wood, and how, when this was neglected, he had dysentery in his strongest colonies early in the winter. He says: "I took off the honey-boards, shoving them forward about 2 inches, and then re-piled the hives. This soon ended the dysentery. Bee-bread may have excited the disease, but ventilation ended it with me." It will be at once seen that the above are clear cases of cures by improved ventilation, giving the bees a chance to dry out. Comment is unnecessary.

Lindsay, Ont., March 7, 1883.

For the American Bee Journal.

Reply to Dr. Tinker.

JAMES HEDDON

I may be in the dark regarding the popularly supposed great advantages of the Langstroth shallow air-chamber above the brood frames, and the surplus receptacles. I may also be in error regarding my supposition that almost all practical producers were enjoying said advantages. I did really think that most of the more experienced bee-keepers, who read our controversy, were laughing at the idea of the barbaric method of resting the sections, or any bar that might support them, down flat on the brood frame top bars.

The Doctor thinks it "strange" that the bees will go through a honey-board and two air-chambers and enter the surplus receptacles just as soon as the flow of nectar begins. Now, Doctor, all that you need is proper arrangements, and the "strangeness" will all resolve itself into simplicity. I would tell you all about these arrangements if it was not for the fact that I am foolish enough to be using these things that I have found best, and tricky enough to be selling just what I use, and you would then accuse me of "advertising."

I am glad that the Doctor and I see nearly enough alike about the half-pound sections, that we mean to give them a trial the coming season.

The Doctor should have quoted some one beside Mr. A. G. Hill as authority in favor of the ancient practice of resting the sections directly on the brood frames. I wonder at his judgment in selection. I have long tried to get a missionary to visit Mr. Hill, but all are afraid of being eaten. Such things have occurred. Well, Doctor, let us leave the matter of the advisability of leaving out the third claim of Mr. Langstroth's invaluable patent to the judgment of the future practice of bee-keepers. It took years to teach us the numerous advantages of this "shallow air-chamber," but we learned it to stay (I think), and it is my sincere conviction that none will do without its splendid features long. Upon this subject, I long ago "cast out the beam," and feel sure the Doctor will cast out his, ere long.

Dowagiac, Mich., April 5, 1883.

Results of My Winter Packing.

E. C. CRANE.

Having had many inquiries concerning the result of my manner of packing, I desire to answer them in the columns of the BEE JOURNAL.

I had 12 colonies, spring count, in 1882; sold 15, and furnished 12 swarms for the woods. I sold 2,000 pounds of comb honey in one and two-pound sections, at an average of 17½ cents per pound, and put 37 colonies into the cellar and 12 on the summer stands, in a shed, open to the south, for the winter, making 49 colonies in all.

I use the improved Quinby hive in preference to four or five other hives I have tried, or any other kind, all things considered. The large (11x18) sensible frames for the brood-chamber, with their two movable division-boards, gives the operator the most perfect control, in directing the energy of his bees to the special object desired, in the different honey flows of the season, enabling him to produce comb honey, extracted honey, or bees, at will. The details of each are supposed to be understood by any old reader of the BEE JOURNAL.

In the fall I select from five to eight of the best brood-frames, with ripe capped honey, on the upper edge and down to the end of each frame, with division-board each side, and blanket or honey-board raised enough for the bees to climb over the tops of the frames; also holes in the combs for runways; then fill with dry leaves, chaff or straw, 3 or 4 inches thick down the sides, to the floor of the hive, and also on the top of the frames, up to the cover, leaving their packing chamber ventilated. I have also used a ventilating chimney with one-inch bore 5 or 6 inches long, with wire screen on top, from the top of the brood-nest to the top of the packing. I do not consider this very essential for cellar packing where the cellar is properly ventilated.

I filled the summer shed with corn stalks a foot deep. I set the hives, packed as above described, one foot

apart, 8 inches from the back side, covering the whole with dry leaves between, behind and on the top, to the depth of 2 feet, leaving the entrance holes open to the south. Those, in the summer house, had a vigorous flight on Jan. 1, 17, 24, 28 and Feb. 4, 11, 17 and 18.

The cellar is 15x30 feet, under a brick house, finished for the purpose, and is clean and dry, with a cement bottom, and it contains nothing but bees. It is ventilated with a 7-inch stove pipe, entering the chimney, 5 feet from the floor, with an elbow running down to within 1 foot of the floor, having a draught sufficient to suck up a dry leaf or small paper from its mouth. I never lost any bees in that cellar. I carried out my 37 colonies on Feb. 27, all strong and in good order. Having sold some, I now have 45 colonies, all containing eggs and brood; some living drones at this writing.

For the American Bee Journal.

Raspberry Honey, Etc.

A. E. FOSTER.

I noticed in the JOURNAL, a few weeks ago, an article asking for information about the quality of honey obtained from raspberry blossom. I believe the article has not been answered yet. I hope some one, who has had a large experience with raspberry honey, will give us "light." I read an item in one of our leading papers, not long since, saying that the honey obtained from raspberries is of an inferior quality, and unfit for the markets.

It looks as though the season had opened in earnest here. To-day, the bees are as busy as can be, bringing in natural pollen. The following is an item about bees in the South laying up stores of honey. Is it true?

Covington, Ky., April 8, 1883.

THE RECKLESS BEE.—An experimenter in Southern agriculture told me the following concerning of Northern bees in the South. He took a colony of the little gratuitous honey-makers down to Florida. The first year they revelled, thrived, and stored honey nearly all the unvaried summer time. But the second year, a few of the more reflective bees evidently turned the thing over in their minds thus: "This country has no winter to provide against; what is the use of laying up honey, where the flowers blossom all the year round?" These bees exerted enough influence among their friends to keep a good many bees from laying by any sweet merchandise the second year of their exile.

But the prudent instinct so strong in the little insect prevailed with the majority. They evidently said to themselves: "Perhaps this has been an exceptional year. Next season may bring cold, and snow, and dearth of flower." So there was quite a stock of honey laid by on the second year, in spite of a few strikers. But by the third year the conviction had evidently

thoroughly penetrated the bee mind that it was foolish to lay up, in a land of eternal blossom. They made just honey enough to last from day to day, and abandoned themselves to living from hand to mouth as recklessly as does the tropic-born butterfly.—*Washington Gazette*.

[No! There is no truth in it. It is but the idle scribbling of a newspaper correspondent, who thought he would get up a sensation by telling an exciting story.—ED.]

For the American Bee Journal.

The Langstroth Frame.

J. B. MASON.

On page 144 of BEE JOURNAL for March 14, Mr. H. D. Edwards criticises my article on page 21 of January 10, 1883. He says I do not state the advantages of the Langstroth frame, and asks why we should adopt it, when the advantages are so few that I have not seen fit to give them. My own idea, formed after long experience with them in my own apiary is, that its advantages are many; in fact, that it contains more real good points than does any other frame; else why is it so fast coming into general use, and that too with practical bee-keepers? Would any one be insane enough to adopt it, if it was not, to say the least, as good as any? I will endeavor now to take up the challenge of Mr. Edwards, and give some of the advantages possessed by the L. frame. First, their now being more largely in use throughout the country than all others combined; by now adopting it, one puts himself on the same track with the great majority, and can easily interchange frames with them, without transferring; as it bids fair to soon become the standard of the country, by using it we are up with the times, and not falling behind. I said it bids fair to become the standard; my reason is, that ere long some standard size will be adopted, and as the Langstroth frame is so largely in use, and so well liked by the unprejudiced, who have given it a fair trial, it will be more easy to adopt it than any other; in fact, it will be utterly impossible to adopt any other as a standard, for all others are now fast giving way to it, and no one will purchase on a falling market.

The reasons why some standard will ere long be adopted, is so patent that I need not take time or space to give them; it is obvious to all that it must come, and when it does, apiculture will take a fresh start. So far as profit is concerned, I care not what style of frame is desired, but I notice that those ordering hives from all sections of New England, at least 95 per cent. of them are for the standard Langstroth, and we may be sure that the climate of New England is pretty severe, to say the least.

My experience is directly opposite to the statement of Mr. E. who says it is generally conceded that bees in a deep frame winter better than in a shallow one.

I admit that it once was the case, and that the American frame 14, and even 16 inches deep, was extensively introduced, but they are fast being thrown out, and their places taken by the Langstroth frame. Experience showing that the wintering qualities of a deep frame was a matter of theory, not well backed up in practice.

The fact that the Langstroth frame can be made more cheaply than any other might be an inducement on the start; but practical men do not care for the slight difference, if they get a better article; so that argument does not carry enough weight to be worth answering. It answers itself at once.

The Langstroth frame has the advantage of being the best and most economical in form, so far as the use of sections is concerned. The sections are placed over the brood chamber, close to the bees, where all the heat of the hive is economized, and the size is such that the space is fully economized and all taken up without loss; this of course is a great advantage, and one that recommends itself to all.

To sum up, the only real objection made to the Langstroth frame is, that it is not best for winter in cold climates. Assertions amount to nothing; it is facts we want. How are the facts, and how do they show up? Mr. E. E. Hasty says it is the best for wintering in cold climates, and he makes the statement from results of experiments in his own apiary. Mr. Bingham says it is too deep, if anything, and he uses (and successfully too) in a cold climate, a frame only 6 inches deep. I apprehend that the objections to the Langstroth frame is largely a matter of prejudice. Some one (no matter who) started the idea in opposition to the Langstroth frame that a deeper frame was better, and the American hives met with large sales; but they are fast being superseded by the Langstroth frame. The public begin to learn that theories put forth by interested parties are not always found, in practice, to be true. With deep frames it is difficult to tier up two or three stories, and this is a serious objection.

The extractor plays so important a part in the management of an apiary, that the best reply I can give to any one who says that the Langstroth frame is too shallow to winter well, is, I do not care whether it is too shallow or not; it does well for wintering, and those who have given it a fair trial say it is better than deeper frames.

I have not space now to give the scientific reasons why a shallow hive, of the depth of the Langstroth, should be better for wintering than a deeper one, but may make that the especial subject of another article; in fact, I do not know as we need to inquire the reasons why a thing should be, when we know that it really is.

The evidence in favor of the Langstroth frame is found in the fact that it is so generally used, and that too by practical men; and in the favorable reports that they make in regard to it; and if the unfavorable criticisms that are made against it were less

theoretical, more strongly backed up by proof, and come more largely than they do from persons not interested in some other style of frame, I should consider them more worthy of confidence, as advice; and of far more weight in favor of their adoption.

Mechanic Falls, March 26, 1883.

For the American Bee Journal.

A Brief but Kind Reply to Prof. Cook.

E. B. SOUTHWICK.

MR. EDITOR.—My article on the one-piece section drew out some remarks from our mutual friend, Prof. Cook, which, in self-justification, requires a brief reply from me.

I am not a Christian, because I am too selfish to love my neighbor as myself. I cannot leave father, mother, wife and children to follow Christ; I love them too well. Can the Professor do this? If so, he may be a Christian, while I am not. But, perhaps, it was the other part of the sentence, that he thought differed from Christian teachings; that is, "Do right because it is right." The Professor has made the mistake of confounding Christianity with morality. Christianity is the name of one of the many religions of the day, while right and wrong existed when all these religions had yet to be brought into being. As to the good and moral examples and teachings of Christ, I am as much of an admirer as Prof. Cook. I can say

"I admire the truth, wherever found.
Whether on Christian or on heathen ground."

For example: I find the golden rule taught by Christ; I admire it there. I find the same taught by Confucius (that heathen Chinese), 500 years before Christ; I admire it there. I find the Bible directs us to honor our father and mother. I also find the same teachings in the old Egyptian religions that were established before the Bible was thought of; and I admire them in both places. All the difference between the Professor and myself, I think, is that he loves the teachers of these, and I love the teachings themselves.

The Professor says I worship right. Well, I think he will admit then that the God I worship is as good as the best, and that he will cheerfully add justice and truth, forming a trinity, over which we can extend to each other the right-hand of fellowship, and unite with Pope in saying:

"What conscience dictates to be done,
Or warns me not to do,
This, teach me more than hell to shun,
That, more than heaven pursue."

Mendon, Mich., April 2, 1883.

[The BEE JOURNAL is "devoted exclusively to progressive bee-culture," and discussions of religion, politics, and many other interesting topics are all inappropriate in its columns. Prof. Cook and Dr. Southwick now have had an opportunity to explain their remarks in a discussion of the patent-section controversy,—let this end the present discussion.—ED.]

For the American Bee Journal.

Those Big Bee Stories.

M. M. BALDRIDGE.

During 1882 the "boys," in various parts of the country, had "lots" of "fun" telling "yarns" about big crops of honey and immense profits by "fooling with bees." Those "boys" in Texas rather got the start of the rest of us and carried off the belt. It is rather early to begin those "yarns" for 1883, but I don't propose to let the Texas "boys" get the start this year, so I will head the list with what one of our "boys" did, as long ago as 1860, to wit:

A TRUE BEE STORY.—On the 1st of February, 1860, the Rev. Hiram Hamilton had 35 colonies of bees near Stockton, California. Twenty-five were in small Langstroth hives, containing about 1,400 cubic inches, and the balance were in larger hives containing about 2,000 cubic inches. At the above date all the bees were moved from Stockton to Santa Clara, California, and they remained there till July 1, just five months—at which date they had increased to 270 colonies. The honey season having closed at Santa Clara, the bees were moved back to the vicinity of Stockton, whence they started, and by Oct. 1, 1860, there were 500 colonies! The 10 colonies in large hives increased to 75 and gave 4,500 lbs. comb honey. The 25 in small hives increased to 425 colonies and gave 16,275 lbs. comb honey! From the 35 original colonies there were at the close of the honey season in 1860, 20,775 lbs. of comb honey, and an increase of 465 swarms, and all of this was secured without purchasing any bees or any feed! They were simply managed skillfully and intelligently, by following the teachings laid down in Mr. Langstroth's excellent book, aided by a magnificent harvest in two very fine locations for honey.

As honey was worth, in California, about \$1.00 per pound in 1860, and as colonies of bees were then in good demand, at about \$100 each, let us see how this figures:

465 swarms, at \$100 each.....	\$46,500
20,775 lbs. of comb honey at \$1.00 per lb.....	20,775
Total.....	\$67,275

This, divided by 35, gives a profit (?) of \$1,922 per colony! Now divide 20,775 lbs. of honey by 35 and we have an average of 594 lbs. of comb honey per colony! It will be seen that the 10 colonies in large hives gave an average of 6½ swarms and 450 lbs. of comb honey per colony; also, that the 25 colonies in small hives gave an average, per colony, of 16 swarms and 651 lbs. of comb honey!

The above discloses the important fact that the small hives were the most profitable for both swarms and honey, which accords with the experience of the best bee-keepers of today. The fact is also disclosed that it does pay sometimes to move bees from one honey range to another.

Inasmuch as I have headed the foregoing as "A True Bee Story," it may now be well, lest some of the "boys" may have some doubts about

it, to cite my authority: Many of the facts enumerated will be found recorded on page 126, first volume of this BEE JOURNAL.

Now "boys" don't let this "yarn" discourage you "one bit," but press on and let us see who will be the first to equal or even surpass, in honey and swarms, the extraordinary success of Mr. Hamilton—for I have my doubts of its having yet been done.

St. Charles, Ill.

For the American Bee Journal.

How to Transfer Bees.

A. RICE.

When it is settled and warm weather, and bees are working finely, take the hive containing the bees to be transferred, to some shady place, or to a work-house away from its own stand, as bees do very little lighting away from home. Immediately place an empty hive or box in the place of hive taken away, to receive the returning bees, thereby keeping the bees from going into a neighboring hive, that might be standing near. Turn the hives to be transferred, bottom side up; notice carefully the condition of the comb, selecting the side of the hive from which the comb can be most readily removed, after which place some box, nail keg, pail, or anything that will partly or fully cover the hive. With hammer and chisel remove the side of the hive selected. Having given the bees a little smoke, a few moments before removal, after removing the side of the hive, a little more smoke may be given, to drive the bees from the first comb, which may then be removed to the frame; return to the hive and proceed as before, until the last piece of comb is taken from the hive, at which time the bees will have transferred themselves to the box or hive at their original home, or have passed up into the box that you placed on the top of the hive. After the best of the comb (leaving most or all of drone comb out) is transferred, take the hive to its original stand, and shake the bees from the box or boxes, on a sheet in front of the hive, as in the swarming season. Very thin splints, from pine or cedar, such as will split finely, should be in readiness, 30 to 40 to the hive, securing two splints to 6 or 8 frames, with small tacks, that they may be easily removed, and ready to receive the comb. After placing the comb, tack two splints on opposite sides of the frame.

From one to three weeks after the bees have secured the comb to the frames, the splints should be removed; after this work is finished, close the hive, so that very few bees can go into the hive at once, lest the bees may be robbed.

Where several colonies are to be transferred, change the transferring stand to a new place, after transferring each one, to keep away from robber bees, which, at times, are very troublesome.

Do you ask when I did the drumming? I did all the drumming necessary in cutting nails and removing

one side of the hive. I can ordinarily transfer a colony while others are drumming the bees.

From taking the hive from the stand and replacing it, as little time as possible should be lost. It is, therefore, very necessary that everything be in readiness, and all done as quickly as possible. It will be observed, that by keeping a box or receptacle on top of the hive, during the transferring, it is nearly or quite impossible to lose the queen, which is of first importance.

Davis Junction, Ill.

For the American Bee Journal.

Selling Honey in My Home Market.

W. C. NUTT.

I have taken quite an interest in the discussions in regard to the merits of the different size of sections. I think we, as producers, should be very careful about changing to a smaller sized section. I have had some experience in furnishing grocery-men with both comb and extracted honey. I have not, as yet, used less than the two-pound section. I was thinking of trying some one-pound boxes this season, but have about concluded to continue with the two-pound sections for the present.

In conversation with a merchant, last fall, I remarked that, perhaps, I would furnish my honey in a little nicer shape the coming year, as I thought that I should use some one-pound sections. He remarked that two-pound boxes were small enough for him to handle. I should expect to sell in my market a two-pound, one-pound, or half-pound section for about the same price per pound.

I use the one and two-pound glass jars for extracted honey; I sell at 15 cents per pound; charging 10 cents extra for jars, and taking them back at the same price. Grocerymen generally sell for me on 10 per cent, commission where cash is paid me after the honey is sold; or even trade, if paid in goods. My two-pound jars seem to have the preference. I am quite sure that the half-pound sections would not pay in my market, and will never be called for unless put on the market.

I examined my bees yesterday; all answered to the roll call, and most of them are apparently in good condition. Some four or five, out of the 66 colonies, show signs of dysentery. I have taken up a considerable number of bees from the floor. I attribute so great a number of dead bees on the floor to the colonies being so strong when put into winter quarters. The cellar is very dry, and is kept dark. For ventilation the outside door is opened occasionally. The winter still hangs on.

Otley, Iowa, March 31, 1883.

The spring meeting of the Cortland Union Bee-keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, Sec.

Convention Notices.

The Mahoning Valley bee-keepers will hold their 13th meeting in the Town Hall, at Berlin Centre, Ohio, on May 5. All bee-keepers, and the public in general, are invited to attend. Do not forget to bring your wives, children, and a well-filled lunch basket. We expect a grand meeting.

L. CARSON, *Pres.*

H. A. SIMON, *Sec. pro tem.*

The semi-annual meeting of the Western Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to bee-keepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, *Sec.*

Kansas City, Mo.

J. A. NELSON, *Pres.* Wyandotte, Kas.

Quite a number of the leading bee-keepers of Missouri and Kansas met at the Court House, in Independence, Mo., December 23, 1882, and organized a bee-keepers' convention, which was named the "Western Bee-Keepers' Association," by electing the following officers for the ensuing year: Jas. A. Nelson, of Wyandotte, Kans., President; L. W. Baldwin, of Independence, Mo., Vice-President; S. W. Salisbury, Kansas City, Mo., Treasurer. The Association passed a resolution to invite all bee-keepers within a convenient distance, to meet with us at our next meeting and lend us their councils. Adjourned, to meet again at Independence, on the last Saturday in April next, at 10 o'clock, a. m. J. D. Meador, P. Baldwin, C. M. Crandall, *Committee.*

The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, *Sec.*

Coopersville, Mich.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, *Sec.*

Christiansburg, Ky.

The Iowa Central Bee-Keepers' Association will hold their semi-annual meeting at Winterset, Iowa, on Friday, May 11, 1883. All interested in anything pertaining to bee-culture are invited to attend, and bring anything that will be of interest to the bee fraternity.

J. E. PRYOR, *Sec.*

A. J. ADKISON, *Pres.*

SELECTIONS FROM OUR LETTER BOX

Bees in Fine Condition.

I imagine all bee-keepers wish to know how bees have endured the past almost unparallel winter. My bees are in fine condition, only two having died, and only one weak.

T. F. BINGHAM.

Abronia, Mich., April 6, 1883.

A Bee Hive 60 Years Old.

I put into winter, last fall, 29 colonies of bees; and they are all right yet, but March has been very hard on bees in this part of the country. It has been cold and freezing nearly all the time. On June 14, 1881, I drove a swarm, for a neighbor, out of a box hive that was 60 years old; it had been put in when the box was new; and when I drove the swarm, it was so rotten I could hardly handle it: there were cracks and holes from top to bottom; it stood the hard winter of 1880-81, without any protection, and the bees were very strong in numbers when I drove the swarm. I cut out a lot of sealed comb out the bottom, and nine days after I had taken the first swarm, it cast a second, and on the eleventh day, it cast a third; this hive had never been known to give a swarm in all the 60 years before. Now, if you have an older bee hive than this one, I would like to hear from it. That bee hive would hold about 2 bushels. The bees are alive and doing well yet, and, of course, that colony will be 62 years old this spring.

WM. ASHCUM.

Ligonier, Pa.

Working on Elder and Maple Blossoms.

My bees had the dysentery this winter, but we had a few very nice days here, and they were all out, and it has cured them. I had 12 colonies last fall, bought 2, and I found 4 colonies dead this spring. The bees are working on elder and maple blossoms.

O. PARKER BAKER.

Woodberry, Md., April 4, 1883.

Bees in Florida.

Bees are hard at work bringing in a bountiful harvest of saw palmetto honey. This harvest will last for two or three months yet; then comes an even better flow from the cabbage palmetto and mangroves, as fine honey as was ever extracted. The prospects are that we will have a very good season this year. I know one bee-keeper here who has extracted over 5 barrels of 45 gallons each from only 23 colonies of black bees, already this year. How does that compare with what bees have done so far this season up North? I consider this region the "No plus ultra" for bee-keepers. We do not discuss "wintering," "dysentery," etc., but "Where can I get barrels to put my money in." The JOURNAL is a most welcome visitor here.

HARRY G. BURNET.

Myers, Fla., April 2, 1883.

Bees Strong and Healthy.

Bees, in this section, have wintered very well, to this date, considering the long confinement to their hives (from Nov. 25 to March 1), and the severe cold weather, 10° to 12° below zero occasionally. The loss of bees on summer stands to April 1, will not be over one-tenth per cent. On Saturday morning, March 31, there was 4 inches of snow, and it was 12° above zero. I have never before known such cold weather on that date of March. I think many bees will need feeding, to save them till blossoms open. They have carried no flour in, to this date. Most of the colonies are strong in bees.

H. H. BROWN.

Light Street, Pa., April 2, 1883.

Bees in the Woods.

Again my bees are on scaffolds and benches on account of the floods. They seem to be in splendid condition, and are bringing in honey and pollen with a rush. I expect soon to have swarms coming out. I would say a word about bees in the woods in Arkansas. While in the woods, a short while back, I found 4 bee trees within 50 yards of one another, and among them was a swarm of well-marked hybrids. This was 12 or 14 miles from my own apiary. I am the only one that has Italian bees in these parts; it would be surprising to any one that has never been in the bottoms of Arkansas, to see the number of bees in the woods. I have found as high as 9 bee trees in a single day. They are mostly yellow bees, with occasionally some hybrids. I intended to say that one of the 4 that I lately found, had built outside of the hollow 2 feet long and about a half dozen sheets, and the bees seemed to be working in it, and also in a hole by the side of the combs.

W. G. MCLENDON.

Lake Village, Ark., March 27, 1883.

Bees in the Cellar All Right.

I put 21 colonies in the cellar, last fall, and they are all right, so far. I gave them a flight in March, and then carried them back to the cellar again, where they are still, and will remain for some time yet. I have practiced the above plan for three winters, and never lost any in wintering yet. All my losses have been from robbing in the fall.

H. H. HAMMOND.

Pre-emption, Ill., April 9, 1883.

Bee-Keeping in Tennessee.

Scientific bee-culture is not known in this country, but a considerable interest is expressed by a few men here. Mr. Wm. Anderson keeps 150 colonies, David England has 24, Elija England 150, Dr. O. G. Broyles 25, Geo. Cole 30, Crockett Lowry 30, Frank Cope 20, myself 16. Most of them in some kind of movable frame hives, but none of them are manipulated very much. There are a great many others who keep bees in log gums. No more honey was gathered, last season, than was consumed, and mine consumed 120 lbs. of sugar, extra. Our principal source of honey here,

for surplus, is poplar from April 25 to May 15; blackberry from April 22 to May 20; June not giving much; then comes sourwood, a great yielder of honey, clear as crystal, during July. Along our mountain caves, linden or basswood comes in June 20, lasting only a week or ten days; on some farms white clover grows profusely, but in my little experience, not much honey has come from it; it blossoms April 30 to Sept. 30. Last year I kept a record of the time of blossoming and of honey yield, of all the different kinds of plants and trees upon which I saw bees at work. The articles of Messrs. Heddon and Doolittle, in the JOURNAL, are just splendid, but they have collided on the building up or stimulating early breeding question.

J. A. P. FANCHER.

Fancher's Mills, Tenn., Mar. 29, 1883.

Swarming in Tennessee.

The honey crop in this section, last year, was a failure; less honey being produced than any year since I have been in the business, which dates back to the year 1874; and, consequently, the loss of colonies, this winter, has been very heavy. Many have lost half; the average loss, I think, will be about one-third. When the winter set in, I had 185 colonies; this spring I still had 140, some of them not doing well, but the most of them in good condition, working finely, bringing in pollen and some honey from peach bloom, and it looks as though the swarming fever was beginning to run over them. One of my neighbors had a fine swarm on the 3d inst.

J. W. HOWELL.

Kenton, Tenn., April 7, 1883.

Bees All Right So Far.

I placed 80 colonies of bees in the cellar on Dec. 7 (a part with top, and apart with bottom ventilation); but as they have all come through without the loss of a single colony, it does not prove anything on that point. My cellar is 22x30; the fire flue extends to the bottom in the centre, with a 6 inch ventilating tube. The thermometer has ranged from 32° to 35°. The loss of dead bees was about $\frac{3}{4}$ of a bushel; our coldest day was March 5, when it was 8° below zero. Those who have wintered their bees on the summer stands, without protection, have lost about 50 per cent. of them. My bees have consumed a very small amount of honey, and are in splendid condition.

C. H. FRANCE.

Erie, Pa., April 9, 1883.

Planting for Honey.

I notice in the BEE JOURNAL, that John H. Martin has made a failure of one of the best honey plants there is (in my opinion), viz.: sweet clover. Having had some experience in sowing, I will give it to the readers of the excellent BEE JOURNAL. In the fall of 1881 I sowed an acre on fresh-plowing, barrowed it over lightly, and awaited the results. In the spring of 1882, not seeing enough young plants to insure a good stand, I sowed the same ground again with the same

amount of seed; also, about $\frac{3}{4}$ of an acre as Mr. M. says, gravelly loam; the result is as good a showing of plants from 6 inches to 2 feet high as any one could desire. It will grow in almost any place, that anything else will grow; even in the fence corners where the soil is never disturbed. I also have had some experience with the Simpson honey plant. Last year I sowed it with catnip, mustard and motherwort, and I have a showing of all of them. The figwort grew 3 or 4 feet high, and after the other bloom had almost entirely failed, the bees were swarming on it until frost stopped them.

J. E. PRYOR.

Arbor Hill, Iowa.

Success in Wintering.

I put into winter quarters, on Nov. 23, 170 colonies of bees (108 in two bee houses, and 62 in the cellar). I took them out of the bee houses on March 1; those in the cellar, on March 9; all in splendid condition except two, which were queenless. Nearly all appear as strong as when put into winter quarters; all have plenty of honey. I use honey-boards, and fill the caps with fine shavings; and give no direct upward ventilation. I have an inch auger hole in the front of the hive, a little above the centre, which is kept covered with perforated tin. I give the same ventilation at the bottom of hive, as I do in summer, and keep the temperature at 42°, as near as possible. I have always had good results when I have wintered in this way; but this winter better than ever. I prefer indoor to outside wintering, and I have tried both.

H. F. PUTNAM.

Galesburg, Ill., April 4, 1883.

Good Work for an Amateur.

We could not do without the BEE JOURNAL; even at three times its cost. We had 2 colonies of black bees in the spring of 1882; increased to 7 by natural swarming and division; have now also 1 colony of Italians. We have lost none this winter (pretty good for an amateur, thanks to the BEE JOURNAL and Cook's Manual), although they were imprisoned for months without a flight, which they enjoyed yesterday and to-day, to the fullest extent. We took 200 pounds of comb honey. We intend to fill 15 hives the coming season. We wintered in a clamp, packed with shavings.

A. C. PARFEY.

Richland Centre, Wis., April 9, 1883.

"Saved the Queen."

As I am one of the many "bee mourners," I am not discouraged yet. I put into winter quarters 18 colonies of Italians, with good stores of honey. Up to date, I have lost seven of that number, and, all but one, left "good estates" of honey. Among the number lost, was my choicest Italian. The queen I purchased from H. A. Burch & Co., in 1881. The 2d of this month I cleaned them up, and in "removing the dead" bees, I found the remains of my prize queen. I carefully removed her to a

shelf in a warm room; after a few hours, to my great surprise, I noticed her crawling up on a pile of papers. I at once made ready to save her, by fitting up a nucleus hive, with three frames, in which I found quite a "good showing" of larvae and young bees; and, to-day, I examined the hive and found a nice supply of eggs.

H. B. HAMMON.

Bristolville, O., April 9, 1883.

Gathering Pollen and Honey.

Our bees are gathering an abundance of pollen and some honey; soft maple, willow and elm are the sources. The condition of our bees are just the reverse of what it was a year ago, at this time. Our 53 colonies all wintered well; with not even a missing queen, so far. The number of weak colonies is small (4 or 5), but all have hatching brood.

S. A. SHUCK.

Bryant, Ill., April 10, 1883.

Wintered Bees on the Summer Stands.

The winter just over, has been a very cold one. I wintered my 30 colonies on the summer stands. About half of them are weak; the rest of them are strong.

V. FISCHER.

Ironton, Wis., April 7, 1883.

Evaporation of Honey.

1. Has the California honey evaporator, mentioned on page 405 of the BEE JOURNAL for 1882, or something similar, been used in the Northwest, and with what success?

2. How long can extracted honey be exposed to air without injury? Should it be bunged up tight to retain its excellence?

3. Can the rank flavor of fall honey be diminished by evaporation, or any other method.

H. W. FUNK.

Bloomington, Ill., April 9, 1883.

[1. Not, that we are aware of.

2. Almost any length of time. It is better to give it air.

3. No.—ED.]

A Lady's Apiary.

I have 39 fine colonies of Italian bees that I manage all by myself. My place covers a half-block. I have my hives all nicely arranged along one side of the lot, except some few along the grape arbors. I find it a most delightful pastime for a lady; so much pleasanter and healthful than doing nothing, all the time, in the house. The swarming season is just beginning.

MRS. DR. E. H. MASON.

Vincennes, Ind.

Bees Carrying Pollen.

Bees have wintered with but little loss here. In the fall of 1880 I put 100 colonies in the cellar; I lost all, by dysentery, but one, and that came through in a very weak condition. The cause was poor honey and long confinement. In 1881 I built up 9 good colonies, which I wintered without loss. I sold two last spring, leaving 7, which I increased to 25 last season. I obtained about 400 pounds of

honey. I lost three, the past winter; they were on the summer stands, under a shed, with straw packed behind and between them, and chaff in top story. They carried in their first pollen on the 6th inst.

P. D. JOHNSON.
Bellmore, Ind., April 11, 1883.

Bees Moved in Winter.

I have examined my bees and find them all in good condition; all have laying queens and brood, and some have drones flying. It will be remembered that I shipped them over 200 miles last fall; then I moved them half a mile on a wagon on Jan. 15, and about March 20, I moved them about 65 miles on a wagon. I sold one and have 17 left, out of 18, in good condition; they are all right, except a few broken combs.

L. G. PURVIS.
Oregon, Mo., April 10, 1883.

Got the Wrong Paper.

I am much pleased with the Weekly BEE JOURNAL, and I think it the best paper published. Wishing to get the Monthly BEE JOURNAL for a friend, I subscribed through a news agent here, and not having your monthly on his list, he sent my dollar to the *American Bee-Keeper* published in Mo. I had to send another dollar to you for the monthly for my friend, for the Mo. paper is utterly useless as a bee paper. Can you not see to it that these subscription agents get your Monthly on their lists as well as the Weekly? Please mention this in the Weekly, and it may save some one else trouble and expense.

R. J. & PHIL OSBURN.
Leclair, Iowa, April 10, 1883.

[Perhaps the best way is to send subscriptions direct to this office. "Subscription agents" often get things mixed, and some of them are perpetual annoyances to publishers by their carelessness in giving addresses, sending the subscriptions to the wrong papers, etc. It is but just to say that there are honorable exceptions. We do not remember a single mistake made by Mr. Doolittle of Borodino, N. Y., or the Subscription News Company of this city. If by chance, a mistake should be made, any honorable publisher would correct it without delay. Our Monthly is on the lists of the principal subscription agents.—ED.]

Almost Discouraged.

Sometime ago, being anxious to see how my bees were (as I had 3 colonies last fall), as soon as I thought it was warm enough, about the middle of the day, I opened the hives to know how the bees were, and found one colony dead, and in the other two I saw no queens; neither am I, at present, able to purchase either queen or colony, and yet, although it is trying, I do not like to say, "class me among the blasted hopes," for I must

try again as soon as I am able, which will not be till sometime in the summer. We have had a sharp winter, sometimes 30° below zero; however, delightful spring is again close at hand, and I trust a beautiful summer will follow.

EDWARD MOORE.
Barrie, Ont.

Offensive Personalities.

MR. EDITOR.—I protest against the manner of discussing questions pertaining to bee culture employed by some correspondents. Friendly controversies upon points of interest to bee-keepers are proper and desirable, but when I read such discussions I want arguments instead of personalities. Nothing can be added to the force of an argument by petty flings respecting the religious opinions of an opponent. It cannot make the slightest difference with the weight of an argument whether the author of that argument believes in this, that or the other "ism," or no "ism" at all. Such methods of discussions are il-liberal and unmanly, and serve only to betray the narrowness of the writer and disgust all candid and fair-minded readers. When a writer has exhausted the facts and arguments on his side of a question he ought to stop, and not rob what he has said of its value (if it has any) by descending to personalities. If he has no facts or arguments to offer, let him leave the space he would otherwise occupy to those who have.

WM. H. FRANCIS.
Frankfort, Mich., April 9, 1883.

[True; one of the most disagreeable things an editor has to contend with is the alarming proneness of human nature to run to "offensive personalities. This is the outcome of a too broad an application of the principle of a "free press." Public men are daily misrepresented and their characters defamed without stint, simply because they are public "targets" for the populace to "shoot at." "Your advice is good and timely," let all remember that while it costs nothing to be polite and kind, it adds much to the comfort and unity of the fraternity.—ED.]

Bees Without a Flight 145 Days.

My 65 colonies of bees are removed from the cellar all in good condition; they were in it 136 days in all; they were without a flight for 145 days.

F. A. SNELL.
Milledgeville, Ill., April 12, 1883.

Abnormal Swarming.

I have had quite a number of bees swarm out, and go in with other colonies during the past day or two; what is the cause? They left lots of honey, a nice batch of sealed brood, larvae and eggs; the combs were nice and clean; in every case, it is about the same. I have captured a few of them, and returned them; one swarm lost its queen, but proceeded immediately

to prepare queen cells, and now have a nice lot of them started. The rest proceed as usual, and are contented. If you can give me some light on this subject, it will be much satisfaction.

A. J. NORRIS.
Cedar Falls, Iowa, April 10, 1883.

[The causes of abnormal swarming are many; but it is the weak colonies that leave their hives. In this case, we imagine, it is the fact that the frames are too full of honey, which are colder than partly empty combs. Sometimes they can be kept from swarming out, by giving them combs containing pollen, if they have none. They would not go away, if there were not some things distasteful about the hives or their surroundings.—ED.]

Bees Packed in Dry Sawdust.

I purchased, in the spring of 1882, 3 colonies of Italian bees; increased by dividing to 9, and extracted a little over 500 pounds of honey. We have had a long severe winter, but all have come through in good condition. I packed them in dry sawdust on their summer stands.

WM. E. HARRIS.
South Bay City, Mich., April 10, 1883.

Southern vs. Northern Queens.

In reply to T. S. Johnson, on page 182, I would say that, last spring, I got two queens from Tennessee, one from Kentucky, and one from Michigan. As far as wintering is concerned, I can see no difference; they are all strong and healthy; the hives are as clean and dry as they were last November. I have about a dozen colonies that have soiled their hives some. I find it the same this spring, as usual; the more pollen in the centre of the hive the more dysentery.

MARTIN EMIGH.
Holbrook, Ont., April 11, 1883.

Prospect in California.

On the 28th and 29th of last month, we had 2 inches more of rain, making 8½ inches for the season. Our bees are in fine condition; no swarms up to this time, but I expect them every day. The weather is fine, and there seems nothing in the way for a moderate valley harvest.

A. W. OSBURN.
El Monte, Cal., April 3, 1883.

Best Report on Wintering.

I set my bees out on the 5th inst., Have wintered 241 colonies, without the loss of a colony; all are in fine condition. The hives are mostly full of bees. If any one has a better report on wintering, let them stand up.

H. R. BOARDMAN.
East Townsend, O., April 13, 1883.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Stimulating Early Breeding.

I would like to have Mr. Heddon answer the following questions:

1. On page 156, BEE JOURNAL, in regard to stimulating early breeding, please explain the proper arrangement of hives necessary to early breeding?

2. What kind of honey board or cover over the frames is best? and of what goods or material made?

3. I use a board made of $\frac{1}{2}$ inch poplar, leaving $\frac{3}{8}$ space between it and the top of the frames. Could I successfully use the feeders you describe, on the top of my hives? My covers are made large enough to come $\frac{3}{4}$ inch down all round the outside of hive, and deep enough to cover 6 inch surplus box.

4. My experience with sweet clover seed has been no more satisfactory than that of Mr. John H. Martin, page 146, BEE JOURNAL. I sowed some early in spring and some late, about April 10; the first on rye, and the last on freshly plowed ground; the latter came up finely and grew till about Aug. 1, after which time I could see no more of it. Give your advice in regard to growing it.

J. A. P. FANCHER.

Fancher's Mills, Tenn.

ANSWERS.—1. Have none but good, normally prolific queens. Such are, in my apiary, the rule. You must not harbor the exceptions. If you use a frame not deeper than the Langstroth, and not more than 8 of them, and keep off all cloths, placing on a board cover with an air space between the cover and the top bars of the brood-frames—with this condition of things no stimulative manipulations are advisable.

2. Do not confound the words "honey-board" and "cover." A honey-board is a perforated board or rack, which supports the surplus honey receptacles, while being filled. A cover is a solid piece, and, as above stated, I prefer a solid board. We use a $\frac{5}{8}$ inch board, and cleated at each end as shown in Fig. 2, letter H, on page 659, of the BEE JOURNAL for 1882. Cover E., as shown in Fig. 1, is about the size, but we have adopted the style of cleating, as shown on shade-board H, Fig. 2. The board is painted all over, and is reversible.

3. Certainly, you can; any of the three feeders I use.

4. I do not feel that my experience with sweet clover, or any other plants, make me the fit person to answer this question. All I can say is, that I should sow melilot clover in early

spring; early enough so that the frost will crack the hard shell, and thus insure more perfect germination. I sow on all sorts of land, and the bees act as though I had done well, when the blossoms appear.

Tiering up Sections.

1. Will the bees bridge from the honey rack to the bottoms of the sections in the case?

2. Will the tops of the sections be soiled, when tiered up?

3. Will the covers blow off?

4. Will not the heat melt the honey in so thin a case?

5. Do you wedge the sections to one side of the case? J. J. HURLBERT.
Lyndon, Ill., April 5, 1883.

ANSWERS.—1. There will be scarcely any bridging between the sections and the honey-board, and the sections and each other.

2. There will be no noticeable soiling.

3. We have no trouble with covers blowing off. We use a 15-pound stone on each shade-board.

4. The shade-board above referred to, breaks the sun's rays from the cases. All hives should be shaded.

5. I do not; wedge all you please, and yet all sections need scraping before crating.

When and How to Use Sections.

Will Mr. Heddon please answer the following questions:

1. When should sections be put on, with reference to beginning of honey season, and strength of colonies?

2. Do you put on a full case of sections at first?

3. Should a case of sections be put on as soon as a swarm is hived? If not, when?

4. Do you use, and deem essential, any other hive cover than the solid honey-board you use?

W. H. FRANCIS.

Frankfort, Mich.

ANSWERS.—1. A good guide for all locations, is when you see new pieces of comb being built between the top-bars and the cover of the hive. This occurs here, generally, when the white clover begins to yield, but sometimes during the flow from cherry, apple and locust trees.

2. Certainly; we put on a full case of 56 pound sections the first thing; the idea that giving the bees a little more room than they will use at first or a little too early will do harm, is not borne out by experiment.

3. When I have a large prime swarm hived on full sheets of foundation, I usually put on one case at once. There is no danger of brood in the sections if the hive and whole arrangement is properly arranged, and often great advantages accrue from so do-

ing. If the swarm is small, the sections will not be needed for 48 hours, and if the frames are empty, or have only foundation starters, usually not before the sixth to eighth day after hiving. Be careful about adjusting the surplus arrangement when you hive the swarm, unless foundation is used in the frames below.

4. I do not use a solid honey-board. There is, and can be no such thing. It is a contradiction in terms. A honey-board is something that the surplus honey rests on while developing, and is always perforated. I use the same cover over the cases that covers the hive,—a "solid board." Over this I use a 2x3 feet shade-board (see cut, Fig. 2, letter H, on page 659, BEE JOURNAL for 1882), and on this a 15 pound stone.

CORRECTION.—"How and What" department for April 11. In my first answer, on page 195, I wish to be understood as saying "no more than one tier high" in the same super or case, but not on the same hive. I believe in and practice the tiering up method, but only one tier of sections in any one case.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Mr. James Heddon announces on another page that he cannot supply any more Hives, etc., in the flat. All interested should notice the advertisement.—*Adv.*

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts each, or \$8 per 100.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

On the next page may be found the advertisement for a "comb foundation fastener," by D. C. Talbot, of Elroy, Wis., to which attention is invited.—*adv.*

Farmers, buy for your daughters one of the celebrated McTammany Organettes that plays any tune. Price only \$8. It will make your home a paradise, and you will never regret it. See illustration in another column.—*adv.*

WANTED—A situation to work with Bees, etc. Address, C. R. Hill, care BEE JOURNAL, Chicago.

SEND POSTAL for my 20 page price list of Italian, Cyprian and Holy Land bees, queens, nuclei and apiarian supplies.

H. H. BROWN, Light Street, Col Co., Pa. 13D3t

The Excelsior Smoker Co.'s Cold Blast gets away with all of 'em. You can handle the most vindictive colony without veil or gloves. Send us \$1 and try it. By mail, postpaid. Address W. C. R. KEMP, Manager, Orleans, Ind. 14D3t

Motherwort & Catnip Seeds WANTED.

I wish to buy a quantity of the above seeds, and invite correspondence with any who can supply them. **ALFRED H. NEWMAN,** 923 West Madison St., Chicago.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., April 16, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 8c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7@9c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12@15c. on arrival.

BEESWAX—Comes in slowly and brings 20@30c per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15@16c. for white, and dark unsalable. Extracted, very little trade is being done in it. 7@9c. is about the market.

BEESWAX—35@36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Buyers are readily obtained for choice comb or extracted at full figures, but off qualities meet with slow sale.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9@9c.; dark and candied, 5@7@9c.

BEESWAX—We quote 30@33c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14@16c.—some inferior sold at 10c.; strained at 6@7c.; extracted at 7@8@8@8c., lots in small packages more.

BEESWAX—Source and wanted at 35c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18@19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17@18c. Extracted very dull at 9@11c.

BEESWAX—None in market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: 1-lb. sections at 30c.; 1-lb. sections, 22@25c.; 2-lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Vandervort Foundation Mill.

6 Inch, Price, \$25.00.

It makes the finest extra thin Foundation for comb honey. For Sale by

Mazeppa, Wabasha Co., Minn.

A10, 14, 16

BE SURE

To send a postal card for our Illustrated Catalogue of Apiarian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the lowest prices. Italian Queens and Bees. Parties intending to purchase bees in lots of 10 colonies or more are invited to correspond.

J. C. SAYLES,

51D15B5t

Hartford, Wis.

1883. YOU GET VALUE RECEIVED! 1883.

QUEENS, BEES AND SUPPLIES

If you want **EARLY QUEENS** from the best improved genuine stock for business; or if you want imported Italian Queens or bees, in full colonies or nuclei, with tested or untested queens; if you want Dunham or Vandervort comb foundation, made from pure beeswax; or if you want hives or apiarian supplies of any kind, send for my new catalogue. It tells you about introducing queens, new "Races of Bees," etc. Cash paid for clean beeswax. Address.

Best work and pure beeswax is warranted. Send for Sample and Circular. 8D1f

W. Z. HUTCHINSON,

Rogersville, Genesee County, Mich.,

has made arrangements to receive Italian queens from the South, early in the season. The queens will be bred from imported mothers, reared by a thoroughly competent and reliable breeder, and, upon their arrival, they will be introduced to nuclei, until needed in filling orders. These queens will be shipped as soon as it is warm enough to this latitude, probably about May 1st, and they will be used in filling all orders for untested queens until about June 15th, when queens reared in the home apiary will be ready to ship. Before June 1st, untested queens will be \$1.50 each; during June, single queen \$1.25, or six for \$6.00; after July 1st, single queen \$1.00, six for \$5.50, twelve for \$10.00. Tested queens (reared last season in the home apiary), before June 1st, \$3.00 each; during June, \$2.50 each; after July 1st, \$2.00 each. Safe arrival guaranteed. Make money orders payable at Flint, Mich. 14D1f

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

"Paraffine Comb" and "Glucose."

It is trite but *true*, that while "Falsehood rides on horseback, truth travels very slowly on foot." We are forcibly reminded of this upon looking over the last annual volume of Appleton's Cyclopædia, published by D. Appleton & Co., of New York. It is very evident that the compiler of that volume has been imposed upon by the notorious Professor Wiley, who, in June, 1881, originated the preposterous falsehood about "comb honey" being sold in New York, the combs of which were "made of paraffine, and filled with pure glucose, by appropriate machinery," etc.

On page 51, of the Cyclopædia mentioned, while enumerating the uses to which glucose had been put, we find the following:

"Glucose is used chiefly for the manufacture of table syrups and candies, for brewing, as food for bees, and for artificial honey."

Glucose is very extensively fed to bees, which eat it with great avidity, and store it away unchanged as honey. It is also put up directly in trade as honey—with which bees have had nothing to do—being put up by means of appropriate machinery into artificial combs made of paraffine."

When this pernicious falsehood first appeared, it was extensively copied by many papers all over this country, and quoted by men of learning and influence, and we endeavored to counteract it, by showing its falsity and absurdity, and calling upon its author for proof. Being hard pressed, this scientific *joker* admitted the absurdity and falsity of his "story," but consoled himself with the idea, that people in general were too thick-

headed to see the "joke," as he stated in the *Indiana Farmer* last June, which was copied into the *BEE JOURNAL* of June 14, 1882, and commented upon.

Mr. Wiley's own version of the origin of the story [lie], and our remarks, are as follows:

Perhaps it may be well enough to give here the origin of the "paraffine comb" story which has appeared, I believe, in almost every publication in the country. The original appeared in the *Popular Science Monthly* for June, 1881, in an article entitled "Glucose and Grape Sugar," which I contributed to that number, and on page 254, occur the following words: "Bees eat glucose with the greatest avidity; or rather, they act as funnels by which the glucose is poured into the comb. For it is quite true that the honey made by bees which have free access to glucose differs scarcely at all from the glucose itself. But the quantity of honey which a bee will store away when fed on glucose, is truly wonderful. This gluttony, however, rapidly undermines the apiarian constitution, and the bee rarely lives to enjoy the fruits of its apparent good fortune. In commercial honey, which is entirely free from bee mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery."

This last clause which, when written, was meant for a *scientific pleasantry*, came near throwing the whole bee world into epilepsy. It appears that persons who devote themselves to *BEE JOURNALS*, undergo a certain cerebral inspiration which renders them incapable of seeing a *joke*. The only point which they can appreciate seems to be the sting of a bee.

The rejoinder reminds us of an anecdote we heard many years ago, located in a rural district in Indiana. A well-to-do farmer lost a very fine filly from his pasture-lot, and after several days' search found it snugly tied in the log barn of a distant neighbor of doubtful repute. The neighbor was indicted, tried, and found guilty of larceny; when the Judge asked what he had to say, why sentence should not be passed, he put in a plea that the animal was only

taken for a joke. The Judge inquired how far his barn was from the pasture lot, to which he replied, "about 5 miles." "Well," said the Judge, "that is carrying a joke too far; hard labor in the penitentiary for seven years." The writer above says he contributed to the *Popular Science Monthly* his "paraffine comb" story [lie] about a year ago, "which has appeared in almost every publication in the country." The latter part of the article, however, was only meant for a *scientific pleasantry*.

Do scientific men indulge in pleasantries which will cast a gloom over thousands of honest producers throughout the country, and depreciate the value of their product by creating a prejudice against it? For nearly a year this *scientific joker* saw his fabrication published in nearly all the papers in the country, and reiterated from across the ocean, and yet he lacked the manhood to affirm it a joke until "the *BEE JOURNAL* man" counteracted its influence by showing the falsity and absurdity of the article. Whether it be true, as has been often intimated, that the story was instigated by parties interested in the glucose traffic, in retaliation for the hostility of the bee men to their frauds, we cannot affirm; but we do believe it originated with no honest intention.

Now we would respectfully call upon Messrs. Appleton & Co., to make the correction in the next annual volume of their Cyclopædia, not only in justice to themselves, but for the sake of truth and right, and thereby aid, as far as possible, to counteract the injury they have already done the honey producers of America, by giving publicity to the fabrication of the self-admitted inventor of the pernicious falsehood; which he says he intended as a "joke" or "scientific pleasantry," but which has been taken in earnest, and copied and quoted as sober facts throughout the world.

When papers like the *Popular Science Monthly*, and books like "Appleton's Cyclopædia" are imposed upon, and unwittingly publish to the world as a fact, what this man, Wiley, well knew was an impossibility, and only the "silly imagination" of an unbalanced mind—is it to be wondered at, that ordinary papers and the common people should be "incapable of seeing the joke?" Evidently Wiley intended the story to make him famous, and cause a sensation! Has he not succeeded, in making fame? Surely; but it is, and should be, written—*infamous!* His "scientific pleasures" are but falsehoods, both unscientific and *unpleasant!* While his "jokes" bear the closest affinity to the senseless jests of odious, and the foolishness of a maniac.

Postage and Money Orders.

According to the new Postal Laws, important changes are to be made during the next few months. In order to save a multitude of questions we will give the main features of the new regulations, which should be studied by all interested.

On and after Oct. 1, 1883, letter postage will be 2 cents for each half ounce or fractional part thereof, between all points in the United States. The rate will then be the same on drop letters and all others. No changes are made in rates on other classes of matter. On and after the 1st of July, 1883, you can obtain at any money order office, postal orders in sums of \$5 and under, by paying a fee of *three cents*. These postal notes will be made payable to bearer without corresponding advices. They will be payable at any money order office within 3 months of the date of issue. After the lapse of that time the holder can obtain the par value, only by applying to the Postoffice Department at Washington. On and after the 1st of July, 1883, you can obtain a postal money order for as large a sum as \$100. The present limit is \$50. The fees on and after that date will be as follows:

Not exceeding \$10.....	8 cents
From \$10 to \$15.....	10 cents
From \$15 to \$20.....	15 cents
From \$20 to \$30.....	20 cents
From \$30 to \$40.....	25 cents
From \$40 to \$50.....	30 cents
From \$50 to \$70.....	35 cents
From \$70 to \$80.....	40 cents
From \$80 to \$100.....	45 cents

The postal notes will be found more convenient in one respect than the fractional paper currency was, since they can be obtained for any number of cents under \$5. There will also be less liability to loss by theft than there was when fractional notes were used for transmission through the mails, especially if the department uses judgment in prescribing the size and form of the notes, and in selecting the paper on which they are to be printed. After the 1st of October the

cost of sending any sum under \$5, by postal note, will be 5 cents—2 cents postage and 3-cent fee.

This will be a great advantage to our subscribers, making a cheap and safe method of sending money in letters for subscription or advertising.

Transferring Bees.—Mr. G. B. Jones, Brantford, Ont., thus describes his method of transferring bees. The special feature of his hive is the arrangement of entrances, which are three in number—one in front, and one at each side, the former being twice as long as the latter. The front one is, of course, essential. The advantages of the others are by him described as follows:

In aid of transferring from an objectionable hive, proceed thus: Place the old hive 3 to 6 inches from the new, with its entrance opposite either side-entrance of the new; construct a closed passage between the two hives; place a piece of D. A. Jones' perforated queen metal over the inner side of the same side-entrance; close the other, leaving the front open; put in the necessary number of combs or foundation for the new hive. Now, drum the bees up from the old hive until the queen leaves it; shake them into the new hive; and, covering both hives, leave them for 21 days. The queen will be unable to get back to the old hive, and will settle down on the new combs, and the bees with her, excepting those which go back to care for the brood. As the brood hatches, it will come forward, and in 21 days all will be out. When honey is scarce, they will take it forward also. Now, remove the old hive, close the side entrance of the new; shake any bees remaining in the old hive in front of the new; and melt the old combs into wax, after extracting what honey they contained. This method has been practised by me with success one summer, and on as late as Sept. 20. Colonies may be doubled much the same way; for having the one common entrance they will soon unite, if scented alike artificially.

Reports from all the States are assuring. The past winter, though severe, has not been a disastrous one. But few losses are reported, and the prospect for a full honey crop is excellent. There is a good sward of clover, having been protected by the liberal amount of snow, and, with a fair amount of propitious weather, there need be no fears of having a poor honey harvest.

Mr. W. H. Furman, for 28 years a resident of Cedar Rapids, Iowa, and during that time one of the most enterprising bee-keepers of Iowa, has taken up his residence in Dakota.

The Bacteria.

We have received a pamphlet of 65 pages, on this subject, by T. J. Burritt, Professor of Botany and Horticulture in the Illinois University. It is a very interesting treatise on the nature, organization, effects and classification of Bacteria. The following extracts from it will give a good idea of the subject matter:

"It is the object of this paper to present, in language freed as far as possible from technical terms, the principal and most interesting facts now known about these silent working denizens of the earth, the air, and the water."

"We swallow them with our food, and at least some kinds sometimes retain their activity in the stomach and intestinal tube. It now seems certain that the latter is always inhabited by special kinds which have to do with the activities there in operation. In health the blood is usually quite free from them, but in certain diseases this too, as it rapidly courses through the arteries and veins, sweeps along in the current myriads of the minute but living and developing, ever active things, inappropriately called "germs."

"There is now, in certain cases, just as good evidence that bacteria cause diseases as there is that hawks destroy chickens, and the evidence is as inductively rigid in the one case as in the other."

We can supply it to any who may desire it at 50 cents.

Virginia for Bee Culture.

It will be remembered that sometime since Mr. E. C. Jordan, at the White Sulphur Springs, Va., advised bee-keepers to try that locality before going further South or West. A correspondent wrote him for particulars, and the reply was sent us for publication, and we have made the following digest of the questions and answers:

Improved farms here are worth from \$15 to \$100 per acre; the main crops produced are wheat, corn, oats, hay, potatoes, fruits, vegetables, etc.; the soil is slate, and there are iron mines here; the Shenandoah Valley is not subject to droughts, and we have no malaria; all kinds of small fruits do first rate here; thousands of cattle, hogs and chickens are raised here, and are shipped to Baltimore, Washington Philadelphia and New York; the best of butter, cream and cheese are produced here; bees obtain surplus here from March to November, and our honey is marketed in Winchester, Washington, Baltimore, Philadelphia and at home, and sells at from 20 to 25 cents per pound.

Advertisements intended for the *BEE JOURNAL* must reach this office by Saturday of the previous week.

CORRESPONDENCE

Rural New Yorker.

The Influence of Food.

PROF. A. J. COOK.

We often hear farmers remark that food has more to do with fine stock than does pedigree. While we do not think this is true, yet we must confess that good feeding is no mean factor in successful stock breeding. Long and careful breeding, indexed by a valuable pedigree, insures susceptibility, which makes great results possible, but only with proper care. A 50-horse power engine possesses great potency, but on one-fourth rations of fuel it would accomplish less than a 10-horse power. Yet it would be foolish to argue that fuel was more important than the style of the engine.

Among higher animals we have no evidence that food produces rapid structural changes. Food, selection and time will change the form, carcass, and even the habits, but only after long years of modification. Among lower animals we have some startling facts that show most graphically that food is sometimes a most powerful agent, able to effect a radical structural change in a very brief time. We all know that, in the main, the animal functions are very similar, even though studied in animals which are structurally wide apart. The now generally accepted philosophy that all animals have a common ancestry should lead us to give wise consideration to the peculiarities of lower animals, even in our treatment of the higher forms. If, then, we can show that food is potent to substantially modify the entire organism and life habits of bees, it should serve to exalt our estimate of its value and influence as affecting the higher animals. The same egg may, yea will, produce either a worker bee or a queen, the character of the progeny depending solely upon the character and quantity of the food consumed. If the food is rich and abundant the result is a queen bee. If it is less nourishing and stinted in quantity, a worker bee is the result. Even after the egg hatches, the young larva may be fed for three days in the meager way, then fed the richer food in ample supply, and a queen will result, though not so valuable a one as though fed the rich royal pabulum in generous quantities from the first.

Now, let us see what the changes are that are wrought by these improved good rations. The queen is longer and slimmer than the worker bees, and her ovaries are feebly developed, capable of growing daily from 2,000 to 3,000 eggs. On the other hand, there is a more feeble development of such organs as are used in procuring food and performing the various operations of the hive. Thus the queen has no pollen baskets, her

jaws, as compared with those of the workers, are weak, her tongue short, and her glandular system and stomach are more fully developed. Thus a simple modification of the food regimen produces sterility in the workers, which are only sterile females, while the organs that are more intimately connected with nutrition are more strongly developed. It would seem that the food is too slight to stimulate the growth of the ovaries, which is appropriated in a more decided development of the special organs which minister to nutrition. If food can do all this with bees, it certainly may be regarded as a very important element in the development and care of our higher animals.

Racks for Surplus Honey.

J. W. PORTER.

I notice some attempts are still being made to get over the difficulty I successfully accomplished years ago, and my plan was illustrated on page 240 of the BEE JOURNAL for 1878. Mr. Whitford's plan on page 56, I see is referred to by Mr. Heddon on page 95.

The purpose was to have a case that would be bee tight; one that could be readily tiered up (a point of great value here), and one that would hold the sections lengthwise of the hive (no other would do for me), and come right down on to the brood combs, with only bee space between sections and brood; one, too, that would admit of long separators of wood. All

Rack for Surplus Honey.

of these points are attained, and the continued use of this rack, for years, have been so satisfactory, that I think a real service will be done to republish the cut of it. It was freely contributed to the fraternity. I had experimented much, and have seen nearly all, including Mr. Heddon's latest; which, while it has some valuable points, is open to serious objections. Mr. Whitford's mistake is in making his T supports solid. Made of X or XX tin, and so bent as to have them thus U, standing $\frac{5}{8}$ inch high, all the strength needed is obtained, and the space permits them to rest on a nail inserted at the apex.

Mr. Heddon asks about bee space. The tin angles are flush with the bottom of the case, and the case rests on strips $\frac{7}{8}$ wide, by $\frac{3}{8}$ thick, placed one at each end, transversely across the brood frames, tight to the ends of the hive. Now, with this arrangement it matters not if the bees build wax bridges in bee space, prying between the case and transverse stick, separ-

ates all without displacing or lifting a comb below. They can be made to fit any hive. At one time I considered it a good advantage to use the deep, wide frame, with hanging separators, and with some bees. Much more can be done with them than with any case. Because of their use in Langstroth frames, I adopted the size of $1\frac{1}{4} \times 5\frac{1}{2} \times 2$ sections; six just fill the frame.

My cases are made to take 18 of them. The separators are notched to let down in the middle tins to bee depth. Five separators only to 18 sections, and each one movable, and of wood or tin may be used. I much prefer wood.

The T should be stamped not hammered. That is done by slitting an oak or hard wood block, strips of tin, $1\frac{1}{8}$ inches wide, are cut and bent slightly into the slot. Then reversed and forced by a lever into the next slot, and they are finished in the shape of this U. An iron or steel square blade of equal thickness is used under the lever. Tinsmiths can form them, but false bends damage the strength greatly.

Charlottesville, Va., Feb. 17, 1883.

Translated from Bienenvater by A. R. Kohnke.

Wax—Tests for Proving its Purity.

PROF. P. F. RESCH, S. J.

What is wax? To the uninitiated this may seem a very superfluous question; but the fact that there are a number of natural products going by that name, demands accurate determination of the kind. For instance, in some churches the ritual directions are to use wax candles at certain ceremonies; the ordinance also specifies of what kind of wax such candles must be made, viz.: "beeswax;" but that is as far as the ordinance specifies. Hence, it is customary to use the product of the native bee, in the different countries where such candles are used; in Europe, it is the common or German bee, or the Italian; in Syria, the Syrian; in Cyprus, the Cyprian; in the East Indies, *Apis dorsata*, *floreæ*, *Indica*; in South America, the species *Gothuir*, *Melipona*, which furnish the wax. It appears that the wax from all the different species of bees possesses the same chemical and physical properties.

For the sake of convenience it has been found necessary to classify wax under the following heads: Beeswax, vegetable wax, and animal wax. On comparing the elementary constituents of the different kinds, we find them to be composed of carbon (C), hydrogen (H), and oxygen (O) in the following average proportions:

Beeswax. . . C, 81.70, H, 13.26, O, 5.04
Veg. wax. . . C, 74.61, H, 12.38, O, 16.01
Min. wax. . . C, 85.70, H, 14.30, O, 0.00

As beeswax, to a great extent, is adulterated, the description of a few handy tests may not come amiss.

Pure beeswax has the following properties: At 30° C, it may be kneaded; between 69° and 70° C, it melts. Its specific gravity is between 0.960, 0.969. A higher or lower spe-

cific gravity indicate adulterations with foreign substances.

Pure wax, when melted, appears as a clear, slightly yellow liquid, and, if put into hot water, should not dissolve the same, nor leave any sediment. This is one of the most important tests, and in order to better observe changes of transparency, or a sediment, should be made in a test tube. But it does not follow that the wax is pure, if no discolored water or sediment is noticed; hence, we have to apply other tests.

Take a piece of caustic lime and slack it in about four times its bulk of water. After it has well slacked, and been well stirred, it must be filtered through filter paper, using a glass funnel for this purpose. Of the now clear lime water obtained, add some to the still molten wax, stirring it well all the time. If now the water becomes whitish or cloudy, or even a sediment is noticed, it indicates adulteration by stearic acid, which combines with the lime, forming an insoluble precipitate of stearate of lime.

A still more delicate test may be performed by dissolving some of the wax in ten times its weight of chloroform, and then adding some of the clear lime solution.

The above are the principal tests. To detect other impurities, which are added to increase the weight and bulk of the wax, but do not combine with it, will not be difficult, and will show themselves by melting the wax. The following substances have been found to be added, to increase the weight: Water, starch, phosphate of lime, sulphate of lime, carbonate of lime, ochre and sawdust.

To adulterate wax the following ingredients are used: Stearine, paraffine, tallow, ceresine (or ozokerit), galipot, and vegetable wax.

To detect water, it is necessary to submit quite a large quantity of the wax to the test of melting, and keeping it at the boiling point, for sometime, to evaporate the water, without burning the wax, of course. Any decrease in weight indicates an admixture of water, the amount of which may be determined by the scales. In the same manner, viz.: by melting, other impurities may be detected, as most, or all of them, will be found as a sediment, either in the wax on the side next to the water, or will even sink entirely to the bottom.

Tallow causes wax to feel fatty or greasy to the touch. One cannot write on such wax with a piece of chalk, while on pure wax it can be done. A little piece of such adulterated wax thrown on a red hot stove, or other iron or burning coals, will emit a heavy, very disagreeably-smelling smoke.

For paraffine, the test is as follows: Take a small piece of the wax, put it into a watch glass, and pour sulphuric acid on. Pure beeswax will be charred, and the paraffine remain without being changed. The same test is applicable with reference to any kind of mineral wax, as ozokerit or ceresine.

If pure wax is put into either, about

half of it will be dissolved, whilst vegetable and mineral wax is entirely soluble in it; with this difference, that the latter, in part, forms jelly flakes. If wax, on being dissolved in either, loses more than half, it contains either vegetable or mineral wax. Youngstown, O.

For the American Bee Journal.

Spring Management of Bees.

FAYETTE LEE.

I am located 60 miles west of St. Paul, on the Manitoba railroad. I have been in the bee business six years; the average yield, per colony, spring count, is 92 pounds. Our surplus honey is from basswood and golden rod. I do not claim that the way I manage bees is perfect, but by putting our experiences together we can learn something. When I first began keeping bees, I borrowed all the bee papers I could find, besides subscribing for three others.

I use a two-story hive with a loose bottom-board. I believe they are the best. I use the American hive, nine frames in each story. Early in April, I put the bees on their summer stands, and raised up every hive and cleaned the dead bees from the bottom board, and closed the entrances half an inch. The next thing is to know if they have honey. I take off the cover and roll back the quilt; if they have capped honey in sight, I close the hive and mark it: "honey for ten days." All hives not having honey in sight, I mark, "short of honey." Beginners should not open a hive when bees need feeding, and tear out all of the frames to see the queen, or ascertain if they have brood. The way I handle weak colonies is: I only take out one frame of comb, just as close to the brood as possible, and in its place I put a frame of honey from some heavy hive, or fill a comb with honey, or syrup made from sugar.

Careless handling is the cause of weak colonies swarming out in early spring; you disturb the bees and queen by handling the brood combs too much; it causes robbing, and out they go, to be killed by trying to enter other hives; tuck them up, warm, till there is plenty of honey and pollen coming in, and then it will do no harm to handle the combs, or look for the queen. I get all the brood possible by the time that fruit and dandelions bloom: by spreading the brood in strong colonies, and taking out now and then a frame of brood, to build up the weak ones. The best moth-trap is a few young turkeys or a pair of ducks: try them and see. As the bees get strong, give them wider entrances; it will not pay to unite weak colonies in early spring; do not think, because they are weak, that the queen is poor; give them brood and bees, and you will see plenty of eggs in a short time.

Early in May I want every hive full of brood, in order to get a large yield of honey from every hive, and a good

increase. I want nine frames of brood in every hive by May 25; and the way to get it done is by spreading the brood combs. I take the outside comb and put it in the centre of the brood-nest; I do this every seven days, until I get nine full of brood. I handle the brood very carefully. In April I have all hives full of brood. If honey is coming in, I get some swarms in May and June, but more in July. I put on the top-story as early as June 1. I have surplus combs in the top story, from the last season, and what I lack is filled by frames of foundation. The increase that gives me the most honey is one swarm from two. I put one frame of brood in the upper story, when I put it on; this causes the bees to go up there to work. I save the queen-cells from the first colony that gives a swarm. In seven days after, I take out all but one frame, and make as many nuclei as I have cells, and take two frames of brood and put with them from other hives. I do this every six days until they are full of brood; as fast as they swarm I return them to their own hive, and take three frames of brood from them, give them a new location, put the three frames of brood in an empty hive, and put it on the old stand. In this way I keep all strong colonies by adding brood. I do not like too much swarming in July; it spoils the honey harvest. By returning them, giving them a new location, and removing some brood, I keep them just where they will give us a large yield of honey. June swarms always pay me best. A swarm will fill its hive with comb in two weeks in June.

Are Half-Pound Sections Desirable?

E. N. WOOD.

As much has been said about the size of sections, I have taken some pains to find out how our bee-keeping friends felt about the matter, in this section of the country, and I have not heard from one that favors the half-pound section, from parties that have a home market for all their product. We all ought to strive to hold to the present sizes of boxes and hives, as changes mean great expense and trouble. It seems to me that a general change in the size of honey boxes will soon bring new styles of hives that will be supposed to be better adapted to the use of the new box, and these new styles will catch many who are young in the pursuit, and as first impressions are strong, many of them would never change; many more sizes would be added to our now standard sizes of hives, frames and boxes. There are four general or standard sizes of boxes, $4\frac{1}{2} \times 4\frac{1}{2}$, $5\frac{1}{2} \times 5\frac{1}{2}$, $5\frac{1}{2} \times 5\frac{1}{2}$, $5\frac{1}{2} \times 6\frac{1}{4}$. The few sizes of boxes now in use has enabled the manufacturers to bring the prices down to the present very low rates, as they make large quantities of each size at a time, whereas, if the half-pound section comes into general use, I think the

prices of them all would be somewhat higher than at present; for get the craze (if I may so call it) once started and it will sweep over the country, and nearly every bee-keeper, no matter what the size his hive may be, will think he must come to the half-pound section as near as possible, and there would be as many sizes of half-pound boxes as there are different sizes of hives at present, and I fear more, as some would reduce their boxes in one way and some in another.

I think, perhaps, for a season or so, the half-pound sections may take well in the market, it being new, and somewhat of a novelty, but it will become a drug upon the market and be driven out of use, to the sorrow of those that have made expensive changes.

Again, I think one-pound is as small a quantity as most people want to buy. It is about the right size to put upon a plate without cutting in two, and if a pound or more of honey is to be bought they would certainly pass by the half-pound lots (for they have the appearance of too much tare) to the 1, 1½ and 2-pound boxes, and, again, I am afraid we cannot get near as large a yield per hive with these small boxes. Let us hear something of this from those that have used them.

North Lansing, Mich.

For the American Bee Journal.

Queens Reared in the South.

THOS. C. DAVIES.

On page 182 of the JOURNAL for April 4, Mr. T. S. Johnson, of Bogart, O., asks Mr. G. M. Doolittle and "any others who have had experience with Southern queens, if he thinks bees from a queen reared in the South are as hardy and well able to stand the long, cold winters of the North, as those from a queen reared here?" Being one of the "others" who have had some experience with Southern queens, I would like to give the following details:

In April of last year I received a dollar-queen from a Southern breeder, and in a few weeks after, a selected tested queen from the same person. I also received a selected tested queen, and a Syrian queen from a New York breeder. From those two selected queens, several fine queens were reared during July and August, and when preparing my bees for the winter, my queens were as follows: Two from the South, two from the State of New York, and 24 reared at home. Several of those were reared the season before the last, and one of them was reared in July, 1879. She had been such an excellent queen, that I had not courage enough to kill her last fall, and she was allowed to live as long as she could. About three weeks ago she died. I suppose of old age.

Twenty of those, including the two from the South, and the selected one from New York, were wintered on their summer stands, well packed in chaff. On April 3, they were all examined, and the two from the South

had their hives well stocked with bees and brood, and fully equal to the one from New York. In fact, those 20 colonies, except one, have wintered admirably, and they are now so equal that I cannot tell which of them is the best.

Of the 8 in the cellar, 6 came through well, but the other two are rather weak, and queenless. One of the queens died last week, and the other, three weeks ago. I united these two, and have sent to the Southern breeder, four days ago, for a queen to give them.

I do not know what has been the experience of others with Southern queens, except that of Mr. Doolittle's with his Texan queen, but I must say that I am well pleased with them so far. I believe with Mr. Doolittle, that "there is a difference in bees about wintering," but can hardly believe, at present, that it is due to the part of the country where they are reared. I sincerely hope that the bee-masters, by "studying and experimenting," will succeed in getting more light on this inequality of different colonies regarding wintering, before another cold winter comes.

Pittsburgh, Pa., April 11, 1883.

Bee-Keeping in Florida.

C. H. LAKE.

As many bee-keepers throughout the country are turning their attention to this State, and being in communication with several prominent bee-keepers already located there, through whom I have gathered the information herein contained. I give it, thinking it might be of service to those about to locate there. For the past three years I have been thinking of removing there permanently, owing to the fact I am of a consumptive family, and suffer extremely with lung difficulty, especially in cold winters in this latitude.

There is a belt of country along the east coast, rightly termed the "Bee Belt." Ten years ago bee-keeping was an unknown industry there, and scarcely a dozen colonies could be found among the few families who then inhabited that portion of Florida. This "belt" commences about opposite Port Orange, extending South as far as Oak Hill, a distance of 125 miles, or thereabout.

Thousands upon thousands of acres of marsh are there covered with the black mangrove, the best and greatest honey producing plant known in Florida. Within this radius the black mangrove predominates, while above the head of Indian river, the red mangrove grows almost exclusively, which, I believe, is not a honey-producing shrub.

This "belt" offers superior inducements to bee-keepers, and when the fact becomes known, bee men will not be backward in availing themselves of the opportunity, by moving in and locating at favorable points. From recent letters from Mr. O. Olson, of New Smyrna, who is, with-

out doubt, the most experienced and successful apiarist in Florida, making bee-keeping his exclusive business, he informs me that it is "impossible to overstock the country." Mr. Olson makes the study of honey-producing flowers a portion of his business, and from "careful microscopic examination of the flowers of the black mangrove," he finds they contain "one-fourth of a drop of honey." When it is taken into consideration that this shrub bears thousands upon thousands of blossoms each season, one can get some idea as to its honey-producing qualities. It is asserted that 90 per cent. of the surplus honey gathered during the season (which lasts usually about ten weeks), is from black mangrove. While there are a great variety of the other honey-producing flowers, blooming at different periods throughout the year, among which can be enumerated the "saw and cabbage palmetto, gallberries, sweet bay, wild sunflowers, yellow jessamine, golden rod, orange bloom, snow vine, basswood, sweet gum, etc., etc." There is no reason why the honey cannot be gathered. With all these natural requisites of building up the colonies to perfection, by the time when the mangrove season opens.

There seems to be a great diversity of opinion among the Florida apiarists in regard to the cabbage palmetto. Some assert that "the bees neither gather honey or pollen from its bloom," while others are equally confident that "it equals in every respect the mangrove, as a honey producer," while others affirm that "it yields pollen only." Different situations probably accounts for the varied results, like many of our own honey-producing shrubs, trees, etc.

Florida has its disadvantages, like all other great honey-producing States, and will, till the tide of immigration is sufficient to establish railroads and water conveyances. New Smyrna is 125 miles from the nearest express office, and for transportation the inhabitants have to "depend on schooners along the coast." A small steamer has been put on between Jacksonville and New Smyrna, for the winter, but is taken off in the spring; this steamer makes one trip a week, but all this will be removed as soon as business springs up, and the country becomes more settled.

Besides "being out of the world," we have the bear, dragon fly, several bee birds, and scores of other enemies to the bee to contend with, and, for that reason alone, we wish the entire country was settled up, while the bee moth reigns supreme, which is owing to the fact that what bees were kept by the old inhabitants, were in the old "gum or moth harbor."

A few more interesting items may not be amiss. W. S. Hart, of Hawks Park, has nearly 100 colonies of bees, and has the best out-fit, consisting of the improved machinery for carrying on the business, foundation machine, evaporating machinery, etc., that there is in Florida.

A. J. Packwood has started with 20

colonies, and has, during last season, taken several thousand lbs. of honey.

H. Olson and Mr. Wilson, from Ohio, seven miles south of New Smyrna, have 184 colonies, the largest apiary in Florida. They make bee-keeping their sole occupation, and are supplied with machinery for the manufacture of hives and everything pertaining to them, and work up an immense amount of lumber during the year. Their bees are mostly Italians, with some hybrids and a few blacks. This seasons crop foots up 25,800 pounds of the best honey we ever sampled.

In regard to the quality of Florida honey, Mr. C. F. Muth, of Cincinnati, who has handled most of the crop produced by these gentlemen, says "he considers their honey the finest ever placed on the market, and that it sells more readily than the white clover honey of the North."

L. H. Bivens, of Glencoe, has 37 colonies, and has shipped, this year, 2,000 pounds. M. B. Rolfe, also of Glencoe, has 8, which has produced 600 pounds.

R. S. Sheldon is one of our oldest bee-keepers. He has, for years past, shipped thousands of pounds of excellent honey, and last year his success was very satisfactory. In the spring he had 53 colonies, increased by artificial swarming to 84, and took thus far, Oct. 1, 6,300 pounds. From a natural swarm lived April 15, 328½ were taken, up to Aug. 15.

Mr. Morrison Lewis, of New Smyrna, is the pioneer in bee-keeping in Florida; that is, he was the first to make bee-keeping pay. He commenced in 1868 with one wild swarm, which he found in the woods, which did finely, increasing to several colonies, besides producing a large amount of honey, the second year, which showed Mr. L. what they were capable of doing, when properly cared for. He received 25 to 30 cents per pound for all his honey, for some eight years. He introduced the first movable comb hive and the first honey extractor into the State, and shipped the first barrel of honey, gathered in Florida, to New York, in 1876. From his 30 colonies, he has shipped, up to Oct. 1, 1882, over 3,000 pounds.

From a private letter received recently from Mr. O. Olson, he states: "I made six swarms from one colony, this season, and took from the old colony 440 pounds of extracted honey. I have, at last, found a climate where I like to stay, in spite of all the insects, which is a great drawback on this coast during June, July and August. A more pleasant and healthy climate cannot be found on earth, and I have lived in Europe and several of the States of America. Smyrna is a place of twelve families, and six miles distant, are twelve more."

I could continue this article to a greater length, but have given the important information sought after by those thinking of going into the business, in Florida. Any further information will be cheerfully given as far as in my power, or by addressing any of the above named gentlemen.

Baltimore, Md., Feb. 12, 1883.

For the American Bee Journal.

Experienced Students of Apiculture.

JESSE OREN.

I cannot see the force of the objections made by Mr. Heddon, page 73, against the views advanced by Dr. Besse in his "advanced step," in recommending diplomas to be given by the North American Apiarian College. It seems to me that Dr. Besse requires of the applicant for honors all that Mr. Heddon requires, and a little more. Mr. Heddon's diploma and "red tape circumlocution," as he calls it, would pass current with the society, and entitle the young man to an examination. Dr. Besse demands an experience of one year in all the manipulations of the apiary. Mr. Heddon, five months, or a bee year, if you please so to call it. Both men are on the same plane in this period of preparation. If Mr. Heddon was one of the examining committee, as he probably would be, and his line of students, with their "red tape," signed "Get there Success," should file into line before the committee, would he not approve them? Would he protest against Dr. Miller's, Doolittle's, Dadant's, Jones', Dr. Besse's, Grimm's "Get there Success?" We believe he would admit all the names to his *ad eundem* list of red tape. They are all well known to the bee world. I am glad they are known, and that they have spoken out. Red tape from any of them would pass a young man into my yard. Still I should prefer the combined red tape of all as being better than of any one alone. One might be all extracted, the other all comb, and half-pound sections at that, too. I might be suited with a mixed husbandry.

Some men are born poets, and must sing; others are born mutes, and cannot sing. There is this difference, also, among bee men. Some few miles from me lives a man who has been "getting there annually" with his 15,000 to 2,000 pounds of honey. He is a local phenomenon, and only known at home. His name is "Get there Success;" but the North American Society knows nothing of him. He has paid \$100 per month for an apiarian assistant; and any red tape he should adopt would pass the owner into my yard as competent. We do not want a private monopoly of red tape, but rather, a good supply from every part of the country. In this way, many who are mutes, will come out of their holes and hold up their hands to be seen.

We hold that red tape does mean something; and that if Mr. Heddon has any, he is proud of it, and would not readily part with it. A graduate of Yale or of Ann Arbor does not imply an illiterate person by any means, but, on the contrary, such graduation is *prima facie* evidence of scholarship, the United States over. We do not expect to make such men as Sir Isaac Newton, Kepler and Leverrier by diplomas, nor, perhaps, such apiarist as Mr. Heddon either; yet this admission does not diminish the significance of diplomas. We are friendly

to Dr. Besse's "advance step," and believe the Society will so look upon the matter, when it meets in Toronto, next autumn. I have just given Mr. Heddon's and Mr. Jones' address to a young man who wishes to learn our business. I have given him a hope that he may be able to meet us at Toronto and pass examination next autumn. With the hope of success, he is going to work the ensuing summer. But like many lawyers and doctors, he may graduate and afterwards make an honorable living hauling manure and digging potatoes.

La Porte City, Iowa.

Haldimand Bee-Keepers' Association

The Haldimand Bee-Keepers' Association held its third meeting on Saturday, March 31, at Nelles' Corners, Ontario, pursuant to adjournment.

Members present, E. DeCew, President; and Messrs. James Armstrong, R. Buckley, Robt. Coverdale, Ephraim Gee, Wm. Abbott, Joseph Carter, Fred. Mehenbacher, E. C. Campbell, R. Anguish, Ambrose Gloyd, James Gloyd, William Harrison, A. Vanderburgh, Wm. Kindree, David Byers, Henry Smith, Elijah Kindree, R. W. Beam, David Anguish.

Minutes of previous meeting read and approved.

The president gave a short address, after which the first question was taken up.

Two Story Hives.—Mr. Armstrong said it depended on the depth of frames; if the frames were shallow, two stories were an advantage; if deep, one story or 1½ stories was about the right thing. Mr. Buckley thought that when extracting, a double story was not necessary.

The Desirable Style of Hive Cover.—The president exhibited one which met with the approval of the members. It was very similar to those now used by D. A. Jones, and is deep enough to allow for a chaff cushion in winter.

Bottom Boards.—Caused considerable discussion. A number of members favoring loose bottoms; others preferring tight bottoms; the majority being in favor of the latter.

Spring Feeding.—The president said the best plan of spring feeding, was that of D. A. Jones, and explained how it should be made. Mr. Byers advocated feeding syrup strained through a cloth; it had worked well. Mr. Vanderburgh thought the best plan of spring feeding was to feed in the fall. Mr. Buckley gave his plan, viz: making a syrup of sugar and flour, pouring it into an empty frame, and putting it in the hive between the cluster. The secretary recommended linseed-cake meal as one of the best substitutes for pollen.

Is it Best that Bees Should Swarm?—Mr. Vanderburgh advocating dividing, as did Messrs. Armstrong and Buckley, and recommended having queens on hand for new colonies. Mr. Kindree thought if the object was to increase, natural swarming was best; if for honey, dividing was best. The

majority gave their opinion in favor of artificial swarming. Messrs. Wm Kindree and Wm. Abbott gave their plans for securing swarms.

How to Rear Good Queens.—Mr. Armstrong preferred rearing queens in a full colony, on full sized frames, and explained his method at some length.

How to Introduce Queens.—Mr. Armstrong recommended the Peet cage, keeping the queen confined until the bees became reconciled to her. The secretary mentioned the plan adopted by Mr. Simmins, of England, who introduced the queen on a frame of bees, with good success.

How to Secure Comb Honey.—Mr. Buckley advocated the use of metal division-boards and section boxes, in the body of the hive. Mr. Gloyd also spoke in favor of that plan, and said it was recommended by prominent bee-keepers. Mr. Kindree was in favor of section boxes in the upper story, leaving the lower story undisturbed.

Register of Each Hive—Its Value.—The president recommended the use of a register for each hive, so that he could tell the condition of his hives without the trouble of examining them every day.

Books and Periodicals.—The secretary advocated the reading of books and periodicals devoted to bee-culture, and thought no progressive bee-keeper should be without one or more good bee papers. In one number of the AMERICAN BEE JOURNAL he had obtained information worth more than the subscription price for a whole year.

Moved by Mr. Armstrong, seconded by Mr. Campbell, that each bee-keeper give a correct report of the number of colonies kept, and the number of pounds of comb and extracted honey from each colony, and what kind of bees.

It was resolved that the next meeting be held on June 16, at 10 a. m., at Cheapside, Ont.

The following statement will show the losses sustained during the past winter:

	Nov. 1882.	April 1883.
Edmund DeCew,	15	5
Robert Buckley,	38	33
James Armstrong,	32	31
Wm. Harrison,	2	2
Ambrose Gloyd,	16	15
Wm. Jack,	8	4
Joseph Carter,	10	9
Robert Coverdale,	6	5
R. W. Beam,	12	9
Wm. Kindree,	15	14
Henry Smith,	2	2
A. Vanderburgh,	9	9
F. Mehlenbacher,	1	1
David Byers,	13	12
Robert Anguish,	37	25
Ephraim Gee,	1	1
E. C. Campbell,	35	32
David Anguish,	4	3
Daniel Rose,	15	7

E. C. CAMPRELL, Sec.

P. S. By the above table it will be seen that the losses during the past severe winter have not been very high, and was caused principally by want of stores. I took mine out of cellar April 9, having been confined for over five months, without a flight.

Three colonies were dead for want of stores; the rest are in good condition, with the exception of two or three, affected with dysentery.—E. C.

For the American Bee Journal

Remarks on Various Matters.

J. O. SHEARMAN.

The wintering problem seems to be pretty well worn; but not finally settled yet. My hobby has been packing in chaff, in which way I have been ordinarily successful. I wintered over 100 colonies, last winter and this, without the loss of a colony so far. I had all of my weakest colonies in the cellar, including some that were intended for doubling up; but the weak and strong all seemed to stand, in the cellar, about alike, except a weak one that had the dysentery; an examination showed that they had only uncapped honey left, though they had sealed honey in the fall. Also two nuclei, with reserved queens, starved. The temperature of the cellar was as near to freezing as I could keep it; it was below only once. I found that when the thermometer indicated near 40° (as often advised through the papers), they would become uneasy. I had only 27 in cellar. Those out of doors, packed in chaff, did well, so far, set close to the ground, on a little bed of straw, for under packing. That goes to show that it is not quite sure death.

I once thought that I had a good thing on them, if only they were covered by snow, and said the deeper the snow the better, with a sloping board over the entrance, of course; but now I have got bravely over that. The winter of 1880-81 was our test on that point. Those deep under the snow were very uneasy, while others situated on the south side of a hill, where the wind blew the snow all away from the front of the hives, came out bright, strong and healthy. That was a damp confinement, while, this winter, though snowed under, 2 feet or more, they came out nearly dry, with much better results. My conclusions are that a number of causes may induce dysentery: 1. Extreme changes of temperature, particularly if damp. 2. Thin honey, more especially if soured by changes of temperature. 3. Long confinement, if in conjunction with either or both of the above unfavorable conditions. 4. Undue breeding while confined, or anything that disturbs them while unable to fly.

On the half-pound sections, my advice is to put a variety of packages upon the market, to supply all kinds of customers; the half-pounds are well enough for part of the supply, but if all the honey was put up that way, it would be no higher in price than if all were in one-pound packages. The novelty helps the price at first.

During the past season I increased only from 90 to 107 colonies; though it was a noted season for swarming, for over two months. I did it, partly, by putting one swarm into another hive, from which a swarm had lately

issued, increasing the surplus room; and partly, before they got so feverish, by gradual extension of the brood-chamber; at the same time, giving more surplus room. The hive I use enables me to do the latter more readily, as the back of the brood-chamber is movable, the same as a division-board, and I can set them to work in three old-fashioned boxes, with two brood frames, or use 18 of the same sized boxes on the top of 12 brood frames.

I have run 12 colonies all through an entire season without swarming, increasing them to 18 by division, and giving them plenty of surplus room. That was four years ago, in a fast-swarming season; but it takes too much time for a large stock to increase a little at a time.

I had the above mentioned 12 colonies in a location where they gathered plenty of the red raspberry honey, while it was too wet for them to do much on the white clover. It was of very fine quality and flavor, though not so light in color as the white clover honey.

New Richmond, Mich., Mar. 6, 1883.

For the American Bee Journal.

Water for Bees in Winter.

EUGENE SECOR.

I suppose some of our Southern brethren, who have been basking in the sunshine for two months, and whose bees have been "out to pasture" so long that they have forgotten the past winter, will shrug their shoulders and thank God that they do not live in this borean land, when we tell them that we are just taking our hives to their summer stands. Well, I suppose the South is a delightful place to live in, but I have yet to learn that they accomplish more in any of the departments of industry during their long summers, than we in the North do in our short ones. A small portion of Texas came to the front last year in the production of honey, but year by year, the North supplies our leading honey markets, with as fine a quality as can be found this side of California. So, while we can successfully compete with them in the production of honey, perhaps we ought not to be so modest in discussing the wintering problems, which, undoubtedly is anything but interesting reading to them.

I have, to-day, taken my bees from the cellar, where they have been since Nov. 13. The last flight they had last fall, was on Nov. 10. This is the longest period I have ever kept them confined without a flight. My experience, to-day, seems to indicate that they could have endured a much longer night. I never before saw bees so cross in the spring. They are usually so glad to get out and fly, to void their feces, that they did not attempt to sting; but, to-day, I was compelled to don bee-vail and gloves, and, in spite of both, I am now far from "spring poor." There are no signs of dysentery. They did not "spot" their hives during the

winter, nor anything around the yard, in their flight to-day. My cellar was perfectly dark, without any ventilation, and ranged, in temperature, during the winter, from 32° to 48°, usually standing at about 45°. It was quite dry. From March 1, I have, several times, watered a part of them, a thing that I never practiced before, but it had the effect to keep them more quiet, and many of them were "just booming" to-day.

Now as to the results: One colony had starved to death. Four out of six, that were on the bottom tier, one foot from the cellar bottom, that had not been uncovered since putting in, and that had had no water, were dead. Only in one hive were the combs moldy, and all had sufficient stores. Those colonies which had been watered since March 1, were strong and healthy, and began to rob in less than an hour after having been set out.

Soft maples, willows, cotton woods, and elms are in bloom. The prairie anemones have been out for some days. The past winter has been one of the coldest known since the early settlement of the State. For about nine weeks from the 20th of December, it hardly thawed on the south side of the house, and the mercury hugged the zero point most of the time, occasionally dropping down to call on numbers 35 and 40. And for fully three months it was too cold for even a healthy bee to venture far from the warmth of the cluster. Fruit trees, in many parts of the State, have been injured; though in this locality we have not suffered in that respect. Bees have also wintered usually well.

Forest City, Iowa, April 16, 1883.

For the American Bee Journal.

Are Bees Taxable?

JESSE OREN.

MR. EDITOR:—On page 42 of the BEE JOURNAL for 1883, you are asked, "Are bees taxable?" Your answer, as given, is in accordance with the facts; but your conclusion is wrong, viz.: property of value is taxable property in Iowa. The statute of a State fixes and names the kinds of property on which a revenue shall be raised. In Iowa, bees are exempt by statute, and about all your patrons here are anxious that you shall so answer. Of course I know that it is not reasonable to expect you to know the laws, etc., of all the States. I have made this matter a special study years ago, and the matter was determined by the Attorney General about 15 years ago, when a special bill was got up by a member of the Legislature, exempting bees, etc. He said that bees were already exempt. But year after year we put in assessors and boards of supervisors who are ignorant of the law, and who reason that all property ought to bear its share of the public burden—good reasoning—but not Iowa law. But who knows any better than you do that the average assessor's judgment as to the value of a colony of bees on the

first day of January is a very poor judgment. He cannot set true values. Enclosed you will find a spicy digest of the subject written by a lawyer of Black Hawk County, Iowa. He had my assistance in the matter. We must, however, fight the battle over and over, year after year. The question is not, "Should bees be taxed in Iowa?" but, "Are bees taxable under our laws?" Please, hereafter, when asked that question, answer, "Not by the laws of Iowa, etc." The BEE JOURNAL, with that answer, will become notorious property, and will be preserved for the eye of the new assessor.

La Porte City, Iowa, Feb. 5, 1883.

ARE BEES TAXABLE?

MR. EDITOR:—Allow me to ask yourself and readers why it was that the board of supervisors of Black Hawk County, on Friday, Jan. 10, adopted Mr. Jenney's classification of taxable property for the year 1879, without first revising it so as to make it legal? I trust that they acted conscientiously in the matter. But will you please, or will somebody please, explain how and where they got their authority for placing bees upon that list? Perhaps our board did not know that they were exempt from taxation in Iowa? Perhaps they have some authority unknown to outsiders? Will somebody please rise and explain?

Now, Mr. Editor, "let us reason together," and see if we can find a little law which is, and ought to be plain, to every reasonable being, at least after it has been pointed out to them. I believe I can show by statute that bees are as plainly exempt as if they had been written in gilt letters at the head of the chapter of exempt property. First, what are bees? Are they vegetables? Are they minerals? Or, are they animals? To which of these kingdoms do they belong? Of course, you and everybody else will say that they are animals, of the insect order. Now, since they are animals, then, as animals, they are twice exempt under the statute. Exempt from taxation, first, by section 797 and 801 of Code of Iowa, 1873. Section 797, division 4, exempts from taxation "animals not hereafter specified." Section 801 enumerates the animals, viz.: "Horses, cattle, mules, asses, sheep, swine." Now, we see that it does not mention bees, nor does it intend for bees to be listed, or it would have mentioned them. At a glance we can see that to have mentioned all the animals exempt would have been an endless task, and when completed would have been a volume of itself, and only merited our ridicule. It might have read like this, viz.: From the animal kingdom there shall be exempt 20 species of the quadrumania, viz.: The buffalo, the elk, the deer, the cat, the dog, the mouse, etc. Of cetacea species, the oyster, the clam, etc. Of birds, the wren, the robin, the swallow, etc. Of reptiles, the lizard, the garter snake, the bull snake, etc. Of insects—30 species—viz.: The hornet, the wasp, the asp, the bee, the bumble bee, and

so on, *ad infinitum*. But the cobra-copella, the rattlesnake, the grizzly bear, the parrot, the seal, the golden fly of South America, owing to the vast amount of money invested in them for show purposes, shall be listed and taxed at twice their appraised value. Such might have been the form of the section had the Legislature attempted it. But they chose a wiser plan, and only enumerated those animals which were to be taxed, and exempted by section 797 all others—bees with the rest.

Again, according to Langstroth and other standard authority, the average life of a working bee, in summer season, is only six weeks, while it is a mooted question whether any worker ever lives to so great an age as seven months. Now, a bee being an animal, under section 821 (last clause), under "classification of property" for taxation, we find that "no entry shall be made on said books of any animal under the age of one year, except swine." The queen-bee is the only bee which lives to so great an age as one year. Her market value is 75 cents, and thousands are annually sold to A. I. Root, of Medina, O., at that price. We find by this section (821) that bees are again exempt. "Well," say some, "it is not the bee, it is the value." To this we again fall back on section 797, where we find "farm produce harvested within one year previous to the listing thereof," is exempt from taxation; and since all that is valuable in a colony of bees, except the 75 cent queen-bee, is harvested "within a year previous to the listing thereof," and comes in exempt along with thousands of bushels of wheat which the farmer may have in his granary or stack, the thousands, yes millions of dollars worth of wearing apparel, including valuable household furniture, thousands of dollars' invested in swine under six months old, calves, colts, chickens, and the like, even down to a \$5,000 shawl, such as Mrs. L.—is said to wear, and other articles of a wardrobe proportionately expensive. From the list of exempt property, it is plain to be seen that it is not the intent of our law to tax all valuable property, for if it did, why exempt so many millions of valuables? In conclusion I would say that I have not talked with any lawyer, who, after a little reference, did not see the exempt condition of bees under our law. I might refer to Clark & Curtis, of Lemars, Ordway, of Waterloo, Judge Gilchrist, of Vinton, the two law firms in our own city, viz.: Bishop & Sharon and Chas. Bishop, and many others whose names I will not occupy time and space to enumerate.

Now, Mr. Editor, please excuse this space-consuming article, as my object in penning this is to aid in the support of the Constitution of the United States and the laws of the State of Iowa. S. A. O.

[We are very glad to make the correction requested. Certainly, on this showing, in Iowa, bees are *not* taxable property.—Ed.]

SELECTIONS FROM OUR LETTER BOX

Are Bees Taxable in Iowa?

Will you please state whether the laws of Iowa exempt bees from taxation? All agree here that if bees are animals they are then exempt. Some think they are insects.

PETER S. TRIEM.

Mt. Auburn, Iowa.

[We are informed that the Attorney General, some 15 years ago, decided that in Iowa bees are not taxable, and according to the laws of that State, they are not assessable. Apiarists in Iowa should show this to the new assessors.—ED.]

Honey Flow in Louisiana.

There has been a fine flow of honey; the bees are in splendid condition. I have been running for increase, and yet from 100 colonies I have taken 3,500 pounds of good honey. I shall start for the North about April 25, with a lot of colonies.

E. T. FLANAGAN.

Kenner, La., April 16, 1883.

A Beginner's Experience.

My father kept bees as long ago as I can remember, and I was always fond of them. About 5 years ago, I and a neighbor procured about a dozen each, and as we had heard of the new way of dividing, we divided them again and again, expecting to get rich in that way, but the winter cleaned us out of the bee business. Taking the advice of a friend, I subscribed for the BEE JOURNAL and bought Cook's Manual, and concluded to try again, after learning more about bees. I sold enough honey to pay for my bees, and all that I had over spent on them, and still have the bees left. They are in good condition now, and will be ready for the harvest when it comes.

Casey, Ill. D. R. ROSEBROUGH.

Wintering Bees, etc.

As dry sawdust is hard to get in the fall, I procured it dry, after harvest, and had plenty in the fall. I have tried chaff with success, but do not want it any more; it harbors mice, and gets damp very quickly. I must either clip the queen's wings or run a great risk of my neck, so I choose the former. I like a deeper frame than the Langstroth, for Canada. I want my frames crosswise; I think a division-board as needful as the hives. I use an outside box about 6 inches larger than the hive, with the entrance bridged, and packed around and on top (with movable side), pressed tight on sawdust. In frosty mornings, in the fall, I remove all outside combs, which can be done very fast, and feed up, on from 5 to 7 frames. Where do bees cluster in the fall and winter? Below the honey; the only

place for them, and just where they should, to give heat for sealing; they have warm honey all winter. I have yet to lose the first good colony prepared in the above manner. I have no carrying to do, in the spring, and bees are packed all the spring, and are not coaxed out, with every sunbeam, to get lost. Two colonies starved, in Langstroth hives, with honey in the hive; sometimes bees cluster in the centre, and getting to the end of the frames in a cold spell, they will starve with honey at the other end. Some of my bees have not flown for 147 days; neither do they seem to want to. They are in excellent condition, with about 5 inches of sawdust on the top. For such a terrible winter, bees that are packed have wintered well. My experience will not agree with that of Prof. Cook, as stated on page 85 of his Manual. In every case, with me, the field bees have decided what shall be done. Last summer I found them keeping the queen from drone cells, and even using violence to stop her from laying drone eggs. I learn from them as to whether there should be a second swarm or not.

CHAS. MITCHELL.

Molesworth, Ont., April 9, 1883.

Willows for Pollen.

I send a shoot taken from a bush or tree, for identification. I find it literally covered with bees, for the sake of the profusion of its pollen. I can liken their labors upon it to nothing else except what we have all witnessed at the rye meal basket. I take it to be a species of the willow, of which Dr. Barrett (1850) enumerated 100 species growing in North America.

WM. S. BARCLAY.

Beaver, Pa., April 17, 1883.

[It is one of the willow family, as you have surmized.—ED.]

My Experience With Bees.

I have had bees for more than 30 years, but never paid much attention to them until the spring of 1879, when I concluded to give them my attention (having quit active business), and to that end, I procured a book on the subject, read the science up, and thought I was master of the situation. Having 5 colonies of black bees I divided them according to instructions in King's Text Book, and succeeded beyond my expectations; in the fall I found myself possessed of 10 colonies in good condition for winter, and got some surplus honey. I put them in the cellar, and they came out all right in the spring of 1880. I again divided and had 20 in the fall, and got a small amount of surplus; all being heavy and in good condition for winter. I thought I would try out-door packing, and packed 10 in oat straw and chaff (after Mr. Heddon's plan), and 10 put in the cellar. March being so pleasant I set set them all out, and unpacked those that were out, all being in good condition, so far as I could see; but April and part of May being wet, cold and windy, they commenced to die off very rapidly, leaving nice clean combs full of honey, so

by the middle of May I had but one weak colony left, which died in the fall, after all my nursing. With over 100 frames full, or partly full of honey, I concluded to try it again, and bought 12 colonies, part hybrids and part blacks, and got one colony from Mr. King, of New York. Increased them to 26, and got 335 lbs. of box honey, which I sold at 20 cents per pound, which paid for the 12 colonies bought. I put them away for the winter, packed in the summer stands, as before, all in good condition. They came out in the spring of 1882 without the loss of a single colony. Expecting big things, I bought \$47 worth of supplies, and increased my stock to 48, by my former method a little modified. Upon examination Oct. 1, I found them nearly all short of winter stores, some not having 5 lbs. of honey, and I got no surplus, except from one colony, and that gave me about 25 lbs. of inferior honey. I did not like to see them die, if I could help it, so I bought two barrels of coffee A sugar, and made it into syrup and fed them, so they averaged in weight from 18 to 30 lbs. I have packed them in plainer shavings. I suppose there never was a worse season for honey in our county before.

WM. B. MCCORMICK.

Uniontown, Pa.

Queen Nursery, Observing Hives, Etc.

Please answer the following questions in the BEE JOURNAL:

1. Seeing that queen nurseries are required for the purpose of having a supply on all occasions when needed, and few bees can be spared for such nurseries, how are they to be protected through the winter; it being necessary to have them strong to keep up heat for winter protection? As high a temperature being as necessary for a weak colony as a strong one, and the natural heat will not be sufficient, how is more heat to be created? I have never seen anything giving instructions on this subject, although Prof. Cook so strongly urges rearing queens.

2. In the observatory hive, as described by Prof. Cook, page 113 of the present volume of the BEE JOURNAL, which, of course, is intended to be in the house, study, or some such place, should not the alighting board be at an open window, for the egress and ingress of the bees, to prevent them coming into the room, where it is desired to see them? I suppose that, during the winter season, the observatory hive may become a queen nursery.

3. What plan must be taken to stimulate late breeding, as urged in Cook's Manual? He gives the advice, but not the information which is necessary to many; in fact to all who have not had the experience in that way. If the bees have plenty of honey, is there something else better for that purpose?

EDWARD MOORE.

Barrie, Ont.

[Prof. Cook replies to the above questions as follows:—ED.]

1. I suppose Mr. Moore means by queen nurseries the small colonies or

nuclei in which the queens are reared. Judge Andrews, of Texas, says queens can be kept caged indefinitely by putting the cage in strong colonies. He says even though the other colonies have queens, the bees will always feed the caged queens. Mr. Alley says in his book, the queens may be thus caged for long weeks, but that there must be feed in the cage; that the bees will not feed them. I have always kept the queens in the small hives or nuclei. By exchanging combs frequently, giving empty cells, the queens are kept active. With a good cellar nuclei can be kept over winter as well as full colonies. The chamber containing them must be small; either a small hive, or, better, the regular hive, with brood-chamber contracted by use of a division board. My brother has kept several nuclei in his cellar the past winter. All but one came through strong. That died of starvation.

2. My observing hive is on a board just outside the window. It is just high enough to be convenient. By lowering the upper sash I can lean on it and study the bees for hours without fatigue. My window is a dormer, so it shades the bees in summer and protects them from storms.

2. I think stimulative feeding is fully described in my Manual. We only need to feed a half pint a day, by the use of any of the feeders described. I think the Smith feeder, illustrated and described in my new Manual (just out) is the best.—A. J. Cook.

The Season in Georgia.

Spring has fairly opened with us at last, but bees are in a backward condition. February was mild and pleasant, and breeding progressed rapidly. March set in cold, and continued so with wet and inclement weather all through. Bees could do nothing, but dwindled fearfully; so by the 1st of April colonies, on an average, were not in as good condition as they were the last of February. Box hive beekeepers have lost heavily.

J. P. H. BROWN.

Augusta, Ga., April 20, 1883.

How to Press and Mount Flowers.

In the Michigan State Fair premium list (apianian department) is offered a premium for the best collection of honey-bearing plants pressed and mounted, or in bloom. Will some one who knows please tell the readers of the BEE JOURNAL how to press and mount flowers?

W. Z. HUTCHINSON.

Rogersville, Mich.

Bees Still in Winter Quarters.

In the spring of 1881, I had 4 weak colonies, and 2 queenless; they increased to 10, and 1 nucleus, fall count; all were packed in chaff. The spring count of 1882, was 9, and 2 queenless. I had from them 500 lbs. of comb honey, and increased to 28; they were all packed in dry goods boxes, with clover chaff. The spring count of 1883, is 27 in splendid condition; I lost one, caused by old bees

and dysentery. My bees are still packed; I expect to leave them so until about May 1, or until the weather becomes settled and warm. My bees are all Cyprians, Italians, and albinos, and I am well pleased with them. I use the A. G. Hill hive, and think it a good one. We have some old fogies here, who keep bees in box hives and briarstone them, etc., and some of them have lost heavily this winter. I could not do without the BEE JOURNAL.

H. HANCE.

Bryon, O., April 16, 1883.

Bees All Right.

I have just unpacked my bees, and find nearly all in booming condition. My loss for the winter has been light. I packed, in my usual way, 165 colonies, and, to-day, I find 160 in good condition. Never did I ever see bees in better condition than mine now are. The hives are nearly full of bees, and in some I find brood in four and five frames, with capped drone brood. The weather has been fine for nearly three weeks. I anticipate a fine crop of honey. The white clover has never looked more promising than it does this spring. Success to the Weekly BEE JOURNAL.

L. J. DIEHL.

Butler, Ind., April 17, 1883.

North Carolina Bloom.

Apples are in full bloom, and clover soon will be. I lost 15 out of 100 colonies, last winter. My bees are very strong at this time, and promise great things, if we have a good season.

J. W. HINSDALE.

Raleigh, N. C., April 13, 1883.

Bees are Just Booming.

I wintered 42 colonies in the cellar, of which I lost 1; of 19 wintered on the summer stands, packed with sawdust, I lost none; leaving me 60 out of 61 colonies. I put them into winter quarters on Nov. 15, and removed them from the cellar, April 10, making about 145 days in the cellar without a flight. There is but little spotting of the hives; all are in fine condition and strong, excepting about 6 which are a little weak, but still are from fair to good colonies. All are gathering natural pollen, to-day, from willows and soft maples, the first this season. The thermometer indicates from 78° to 82°, and it is raising quite briskly this evening, at 8 o'clock.

U. E. DODGE.

Fredonia, N. Y., April 15, 1883.

How to use Bee Papers.

I think the printers have scarcely followed "copy," or I have made a strange blunder in my communication, published in the BEE JOURNAL, March 28, page 166, third paragraph. I intended to have written: "Any man who cannot make his business pay for a good journal published in the interest of that business, had better quit the business, etc." or words to that effect. It now, however, reads: "Any man who cannot make his business pay had better quit the business, etc." You will at once

see the difference. The latter quotation, I presume, goes without asking by the necessities of the case, and does not need a special communication to state it, but while the former may be equally as true, yet it is so often in practice ignored as to need a reminder.

R. J. KENDALL.

Austin, Texas, March 30, 1883.

[It was printed as written in the copy.—ED.]

Bees Confined 159 Days.

On page 180, Mr. McKay says who can beat 130 days without a flight? Well, I can. My bees have been in the cellar 159 days without a flight, and have some 10 days more to remain, at least. All answered to the roll call to-day. "21 in number;" loss, thus far, none. The dead on the floor can all be put into a two-quart measure. The above success is due, in a great measure, to the AMERICAN BEE JOURNAL, of which I have been a constant and interested reader for three years, and never expect to do without it as long as I keep bees. I use chaff mats, and am a strong believer in cellar wintering.

D. L. HERRICK.

Brattleboro, Vt., April 15, 1883.

A Swarm Went to the Woods.

I had 4 colonies of bees in boxes and barrels. Three of them I transferred more than a month ago, in the ordinary way. The boxes broke, and induced robbing, and I had so much trouble that I determined I would let the fourth wait and swarm. But seeing Mr. Heddon's plan, I concluded to try it, especially as the weather was warm, apples, clover, etc., blooming, and several colonies of my neighbor's bees had swarmed during the last few days. I very soon drove the bees into the hive filled with comb foundation; they remained several hours, and took their departure to the woods. I hope others may profit by my experience.

A SUBSCRIBER.

Omega, La.

Stinging and Dislike of Bees.

The bees have a natural dislike to me; they come for me quickly, even when walking in the yard, but not at work with them. One sting will sometimes almost cause me to faint. The rule, that the more a person gets stung, the less it hurts, does not hold good with me; the pain is as severe as it was five years ago. I wear veil and gloves, and have a Bingham smoker, but I get stung often. To allay the pain, after the sting, wet clay is the best thing I have ever tried. The best antidote I have ever tried is whisky; two teaspoonsful before I go to work with the bees. I am not used to whisky, and do not want to be; I hate it. Will some of the readers of the JOURNAL tell me what, if anything, I can put on my clothes to pacify them; and what is the best antidote besides whisky, and oblige one who cannot follow hard labor, and do not want to throw away what it has taken 15 years to learn.

Riverton, Iowa. J. H. STEPHENS.

Convention Notices.

The Mahoning Valley bee-keepers will hold their 13th meeting in the Town Hall, at Berlin Centre, Ohio, on May 5. All bee-keepers, and the public in general, are invited to attend. Do not forget to bring your wives, children, and a well-filled lunch basket. We expect a grand meeting.

L. CARSON, *Pres.*

H. A. SIMON, *Sec. pro tem.*

The semi-annual meeting of the Western Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to bee-keepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, *Sec.*

Kansas City, Mo.

J. A. NELSON, *Pres.* Wyandotte, Kas.

Quite a number of the leading bee-keepers of Missouri and Kansas met at the Court House, in Independence, Mo., December 23, 1882, and organized a bee-keepers' convention, which was named the "Western Bee-Keepers' Association," by electing the following officers for the ensuing year: Jas. A. Nelson, of Wyandotte, Kans., President; L. W. Baldwin, of Independence, Mo., Vice-President; S. W. Salisbury, Kansas City, Mo., Treasurer. The Association passed a resolution to invite all bee-keepers within a convenient distance, to meet with us at our next meeting and lend us their councils. Adjourned to meet again at Independence, on the last Saturday in April next, at 10 o'clock, a. m. J. D. Meador, P. Baldwin, C. M. Crandall, *Committee.*

The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, *Sec.*

Coopersville, Mich.

The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, *Sec.*

Christiansburg, Ky.

There will be a meeting of the bee-keepers of Western New York and Western Pennsylvania, to adopt a constitution and by-laws, elect officers, etc., for the Western New York Bee-Keepers' Association, on April 28, 1883, at Fredonia, N. Y., opening at 10 o'clock a. m. All bee-keepers are cordially invited to attend. Discussions on bee-culture, etc. Suitable rooms will be provided.

U. E. DODGE, *Acting Sec.*

The Tuscarawas Valley Bee-Keepers' Association will hold their next meeting in the Town Hall, Coshocton, O., on Wednesday, May 2, at 10 a. m. All bee-keepers are requested to be present.

J. A. BUCKLEW, *Sec.*, Clarks, O.

The spring meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, *Sec.*

The Iowa Central Bee-Keepers' Association will hold their semi-annual meeting at Winterset, Iowa, on Friday, May 11, 1883. All interested in anything pertaining to bee-culture are invited to attend, and bring anything that will be of interest to the bee fraternity.

J. E. PRYOR, *Sec.*

A. J. ADKISON, *Pres.*

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., April 23, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 6c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7½c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12½c. on arrival.

BEESWAX—Comes in slowly and brings 20¢@30¢ per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15¢@16c. for white, and dark unsalable. Extracted, very little trade is being done in it. 7½c. is about the market.

BEESWAX—35¢@36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Buyers are readily obtained for choice comb or extracted at full figures, but off qualities meet with slow sale.

White comb, 14¢@17c.; dark to good, 11¢@13c.; extracted, choice to extra white, 8¢@9½c.; dark and candied, 5¢@7½c.

BEESWAX—We quote 30¢@33c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14¢@16c.—some inferior sold at 10c.; strained at 6½¢@7c.; extracted at 7½¢@8½c., lots in small packages more.

BEESWAX—Scarce and wanted at 35c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18¢@19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17¢@18c. Extracted very dull at 7½c.

BEESWAX—None in market.

A. C. KENZEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22¢@25c.; 2 lb. sections, 20¢@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone, we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Mr. James Heddon announces on another page that he cannot supply any more Hives, etc., in the flat. All interested should notice the advertisement.—*Adv.*

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new Recipes for Honey Medicines*, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

An Instantaneous Light.

Such in a word is the unique apparatus on exhibition at the rooms of the Portable Electric Light Co., 22 Water Street, Boston. It occupies the space of only 5 square inches, and weighs but 5 pounds, and can be carried with ease. The light, or more properly lighter, requires no extra power, wires or connections, and is so constructed that any part can be replaced at small cost. The chemicals are placed in a glass retort; a carbon and zinc apparatus, with a spiral platinum attachment, is then adjusted so as to form a battery, and the light is ready. The pressure on a little knob produces an electric current by which the spiral of platinum is heated to incandescence. The Portable Electric Light Company was recently incorporated, with a capital of \$100,000, under the laws of Massachusetts. The usefulness of the apparatus and the low price (five dollars) will no doubt result in its general adoption. Some of the prominent business men of the State are identified with this enterprise. In addition to its use as a lighter, the apparatus can also be used in connection with a burglar-alarm and galvanic battery. — "Boston Transcript," Dec. 30.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Will the various manufacturers of the Standard Langstroth hive please send circulars giving accurate dimensions, as made by them, to S. X. Clark, Delavan, Wis. The result as to the different sizes will be published in the AMERICAN BEE JOURNAL.—*adv.*

New Catalogues and Price Lists.

We have received the following new Catalogues and Price Lists of Bees, Queens or Apiarian Supplies:

G. B. Jones, Brantford, Ont.
 Elvin Armstrong, Jerseyville, Ill.
 Geo. W. Baker, Lewisville, Ind.
 Dr. Wm. R. Howard, Kingston, Tex.
 W. G. Russell, Millbrook, Ont.
 J. H. Tilley & Bro., Castle Hill, Me.
 Thos. J. Ward, St. Mary's, Ind.
 C. R. Mitchell, Hawkinsville, Ga.
 G. H. Knickerbocker, Pine Plains, N. Y.
 A. C. Kendel, Cleveland, O.—field, garden and flower seeds.

In Mr. S. Corneil's excellent article on "Ventilation of Bees," in last week's JOURNAL, on page 200, an omission was made, when putting it in type. In the second column, 28th line from the top, after the period, add the following sentence: "It is just so with the air."

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

On the next page may be found the advertisement for a "comb foundation fastener," by D. C. Talbot, of Elroy, Wis., to which attention is invited.—*adv.*

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Golden Italians Again!

One Golden Italian Queen, warranted purely mated, \$1.50. One purely mated and tested, \$2.50. One pure Queen, not warranted, \$1.00. All the above Queens are of the best stock in the country. I sold over 30 last season, and had but one complaint. Full colonies ready to divide, for \$10.00; safe arrival guaranteed. 17A11

1883 ITALIAN QUEENS. 1883

Still they go—Bees for business all ready to ship. Send for our new Circular of Queens, full colonies and nuclei; it tells how to introduce queens.

T. S. HALL,
 Kirby's Creek, Jackson co, Ala.

Bee-Keepers' Handy Book,

Or, 22 Years' Experience in Queen Rearing.

Opinions of Eminent Apiarists of its value:

From Geo. W. House, Fayetteville, N. Y.—"The information gained by a careful study of the new method of Queen Rearing, I consider worth \$100 to me. It supplies a long felt want to every Queen breeder and dealer, and is invaluable to any bee-keeper."

From James T. Norton, Winsted, Conn.—"I have read your book with much satisfaction and profit; it is written concisely and to the point. It should be in the hands of every bee-keeper."

From Rev. D. D. Marsh, Georgetown, Mass.—"Your book on Queen Rearing has been received. I am very much pleased with it. It is refreshing to see how frankly you have divulged the hard-earned secrets of your long experience. Your book contains a great deal of that information, which those who have already taken the 'first lessons' in apiculture will find new and valuable."

It will be remembered that Mr. E. T. Flanagan, of Belleville, Ill., went to Kenner, La., in March last to rear early Queens. After receiving the book he wrote me thus:—"I would have cheerfully given \$50.00 to have had your book and apparatus here when I first came. I am rearing 300 Queens."

From L. C. Root, Mohawk, N. Y., and one of the most prominent apiarists in America.—"Your book has been received. Its title, 'TWENTY-TWO YEARS' EXPERIENCE IN QUEEN REARING,' is enough to convince any bee-keeper that they cannot afford to be without it. Good Queens are the rock upon which bee-keeping rests. I predict a large sale for the work."

From J. M. Hicks, editor of the bee department, American Grange, Bulletin. Mr. Hicks is well known to nearly all bee-keepers in the west.—"Book received. I pronounce it the best work of the kind, of American publications. I consider it a perfect gem for the practical bee-keeper, and should be in the hands of every apiarist."

Until May 1st the book will be sold for \$1.00 per copy. After that date, \$1.25 per copy, handsomely bound in cloth, and \$1.00 bound in paper. Fractionable parts of a dollar can be sent in postage stamps.

Our new circular and price list of Queens for 1883 contains 32 pages, and is illustrated to show our new way of rearing Queens. Send your address on a postal card for it.

HENRY ALLEY, Wenham, Mass.

FOR EXCHANGE.

Comb Foundation Machine for pure Italian Bees. Address, S. LONGLEY, CINCINNATI, O. 17A 1t.
 In perfect order.

The Bee-Keepers' Guide,

OR, MANUAL OF THE APIARY.

9,000 SOLD IN SIX YEARS.

10th Thousand Just Out.

More than 50 pages, and more than 50 fine illustrations added. The whole work has been thoroughly revised, and contains the very latest in respect to bee-keeping. It is certainly the fullest and most scientific work treating of bees in the world.

I had hoped and expected to make the price one dollar, and it has been so advertised by Mr. James Heddon and in Alley's new book; but owing to the increased size and expense, this is impossible.

PRICE, BY MAIL, \$1.25.

Liberal discount to dealers and to clubs.

BEE JOURNAL

VOL. XIX.

CHICAGO, ILL., APRIL 25, 1883.

No. 17.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

"Paraffine Comb" and "Glucose."

It is trite but *true*, that while "Falsehood rides on horseback, truth travels very slowly on foot." We are forcibly reminded of this upon looking over the last annual volume of Appleton's Cyclopædia, published by D. Appleton & Co., of New York. It is very evident that the compiler of that volume has been imposed upon by the notorious Professor Wiley, who, in June, 1881, originated the preposterous falsehood about "comb honey" being sold in New York, the combs of which were "made of paraffine, and filled with pure glucose, by appropriate machinery," etc.

On page 51, of the Cyclopædia mentioned, while enumerating the uses to which glucose had been put, we find the following:

"Glucose is used chiefly for the manufacture of table syrups and candies, for brewing, as food for bees, and for artificial honey."

Glucose is very extensively fed to bees, which eat it with great avidity, and store it away unchanged as honey. It is also put up directly in trade as honey—with which bees have had nothing to do—being put up by means of appropriate machinery into artificial combs made of paraffine."

When this pernicious falsehood first appeared, it was extensively copied by many papers all over this country, and quoted by men of learning and influence, and we endeavored to counteract it, by showing its falsity and absurdity, and calling upon its author for proof. Being hard pressed, this scientific *joker* admitted the absurdity and falsity of his "story," but consoled himself with the idea, that people in general were too thick-

headed to see the "joke," as he stated in the *Indiana Farmer* last June, which was copied into the BEE JOURNAL of June 14, 1882, and commented upon.

Mr. Wiley's own version of the origin of the story [lie], and our remarks, are as follows:

Perhaps it may be well enough to give here the origin of the "paraffine comb" story which has appeared, I believe, in almost every publication in the country. The original appeared in the *Popular Science Monthly* for June, 1881, in an article entitled "Glucose and Grape Sugar," which I contributed to that number, and on page 254, occur the following words: "Bees eat glucose with the greatest avidity; or rather, they act as funnels by which the glucose is poured into the comb. For it is quite true that the honey made by bees which have free access to glucose differs scarcely at all from the glucose itself. But the quantity of honey which a bee will store away when fed on glucose, is truly wonderful. This gluttony, however, rapidly undermines the apian constitution, and the bee rarely lives to enjoy the fruits of its apparent good fortune. In commercial honey, which is entirely free from bee mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery."

This last clause which, when written, was meant for a *scientific pleasantry*, came near throwing the whole bee world into epilepsy. It appears that persons who devote themselves to BEE JOURNALS, undergo a certain cerebral inspiration which renders them incapable of seeing a *joke*. The only point which they can appreciate seems to be the sting of a bee.

The rejoinder reminds us of an anecdote we heard many years ago, located in a rural district in Indiana. A well-to-do farmer lost a very fine filly from his pasture-lot, and after several days' search found it snugly tied in the log barn of a distant neighbor of doubtful repute. The neighbor was indicted, tried, and found guilty of larceny; when the Judge asked what he had to say, why sentence should not be passed, he put in a plea that the animal was only

taken for a joke. The Judge inquired how far his barn was from the pasture lot, to which he replied, "about 5 miles." "Well," said the Judge, "that is carrying a joke too far; hard labor in the penitentiary for seven years." The writer above says he contributed to the *Popular Science Monthly* his "paraffine comb" story [lie] about a year ago, "which has appeared in almost every publication in the country." The latter part of the article, however, was only meant for a *scientific pleasantry*.

Do scientific men indulge in pleasantries which will cast a gloom over thousands of honest producers throughout the country, and depreciate the value of their product by creating a prejudice against it? For nearly a year this *scientific joker* saw his fabrication published in nearly all the papers in the country, and reiterated from across the ocean, and yet he lacked the manhood to affirm it a joke until "the BEE JOURNAL man" counteracted its influence by showing the falsity and absurdity of the article. Whether it be true, as has been often intimated, that the story was instigated by parties interested in the glucose traffic, in retaliation for the hostility of the bee men to their frauds, we cannot affirm; but we do believe it originated with no honest intention.

Now we would respectfully call upon Messrs. Appleton & Co., to make the correction in the next annual volume of their Cyclopædia, not only in justice to themselves, but for the sake of truth and right, and thereby aid, as far as possible, to counteract the injury they have already done the honey producers of America, by giving publicity to the fabrication of the self-admitted inventor of the pernicious falsehood; which he says he intended as a "joke" or "scientific pleasantry," but which has been taken in earnest, and copied and quoted as sober facts throughout the world.

When papers like the *Popular Science Monthly*, and books like "Appleton's Cyclopedia" are imposed upon, and unwittingly publish to the world as a fact, what this man, Wiley, well knew was an impossibility, and only the "silly imagination" of an unbalanced mind—is it to be wondered at, that ordinary papers and the common people should be "incapable of seeing the joke?" Evidently Wiley intended the story to make him famous, and cause a sensation! Has he not succeeded, in making fame? Surely; but it is, and should be, written—*infamous*! His "scientific pleasantries" are but falsehoods, both unscientific and *unpleasant*! While his "jokes" bear the closest affinity to the senseless jests of odious, and the foolishness of a maniac.

Postage and Money Orders.

According to the new Postal Laws, important changes are to be made during the next few months. In order to save a multitude of questions we will give the main features of the new regulations, which should be studied by all interested.

On and after Oct. 1, 1883, letter postage will be 2 cents for each half ounce or fractional part thereof, between all points in the United States. The rate will then be the same on drop letters and all others. No changes are made in rates on other classes of matter. On and after the 1st of July, 1883, you can obtain at any money order office, postal orders in sums of \$5 and under, by paying a fee of *three cents*. These postal notes will be made payable to bearer without corresponding advices. They will be payable at any money order office within 3 months of the date of issue. After the lapse of that time the holder can obtain the par value, only by applying to the Postoffice Department at Washington. On and after the 1st of July, 1883, you can obtain a postal money order for as large a sum as \$100. The present limit is \$50. The fees on and after that date will be as follows:

Not exceeding \$10.....	8 cents
From \$10 to \$15.....	10 cents
From \$15 to \$20.....	15 cents
From \$20 to \$30.....	20 cents
From \$30 to \$40.....	25 cents
From \$40 to \$50.....	30 cents
From \$50 to \$70.....	35 cents
From \$70 to \$100.....	40 cents
From \$100 to \$1000.....	45 cents

The postal notes will be found more convenient in one respect than the fractional paper currency was, since they can be obtained for any number of cents under \$5. There will also be less liability to loss by theft than there was when fractional notes were used for transmission through the mails, especially if the department uses judgment in prescribing the size and form of the notes, and in selecting the paper on which they are to be printed. After the 1st of October the

cost of sending any sum under \$5, by postal note, will be 5 cents—2 cents postage and 3-cent fee.

This will be a great advantage to our subscribers, making a cheap and safe method of sending money in letters for subscription or advertising.

Transferring Bees.—Mr. G. B. Jones, Brantford, Ont., thus describes his method of transferring bees. The special feature of his hive is the arrangement of entrances, which are three in number—one in front, and one at each side, the former being twice as long as the latter. The front one is, of course, essential. The advantages of the others are by him described as follows:

In aid of transferring from an objectionable hive, proceed thus: Place the old hive 3 to 6 inches from the new, with its entrance opposite either side-entrance of the new; construct a closed passage between the two hives; place a piece of D. A. Jones' perforated queen metal over the inner side of the same side-entrance; close the other, leaving the front open; put in the necessary number of combs or foundation for the new hive. Now, drum the bees up from the old hive until the queen leaves it; shake them into the new hive; and, covering both hives, leave them for 21 days. The queen will be unable to get back to the old hive, and will settle down on the new combs, and the bees with her, excepting those which go back to care for the brood. As the brood hatches, it will come forward, and in 21 days all will be out. When honey is scarce, they will take it forward also. Now, remove the old hive, close the side entrance of the new; shake any bees remaining in the old hive in front of the new; and melt the old combs into wax, after extracting what honey they contained. This method has been practised by me with success one summer, and on as late as Sept. 20. Colonies may be doubled much the same way; for having the one common entrance they will soon unite, if scented alike artificially.

 Reports from all the States are assuring. The past winter, though severe, has not been a disastrous one. But few losses are reported, and the prospect for a full honey crop is excellent. There is a good sward of clover, having been protected by the liberal amount of snow, and, with a fair amount of propitious weather, there need be no fears of having a poor honey harvest.

 Mr. W. H. Furman, for 28 years a resident of Cedar Rapids, Iowa, and during that time one of the most enterprising bee-keepers of Iowa, has taken up his residence in Dakota.

The Bacteria.

We have received a pamphlet of 65 pages, on this subject, by T. J. Burrill, Professor of Botany and Horticulture in the Illinois University. It is a very interesting treatise on the nature, organization, effects and classification of Bacteria. The following extracts from it will give a good idea of the subject matter:

"It is the object of this paper to present, in language freed as far as possible from technical terms, the principal and most interesting facts now known about these silent working denizens of the earth, the air, and the water."

"We swallow them with our food, and at least some kinds sometimes retain their activity in the stomach and intestinal tube. It now seems certain that the latter is always inhabited by special kinds which have to do with the activities there in operation. In health the blood is usually quite free from them, but in certain diseases this too, as it rapidly courses through the arteries and veins, sweeps along in the current myriads of the minute but living and developing, ever active things, inappropriately called "germs."

"There is now, in certain cases, just as good evidence that bacteria cause diseases as there is that hawks destroy chickens, and the evidence is as inductively rigid in the one case as in the other."

We can supply it to any who may desire it at 50 cents.

Virginia for Bee Culture.

It will be remembered that sometime since Mr. E. C. Jordan, at the White Sulphur Springs, Va., advised bee-keepers to try that locality before going further South or West. A correspondent wrote him for particulars, and the reply was sent us for publication, and we have made the following digest of the questions and answers:

Improved farms here are worth from \$15 to \$100 per acre; the main crops produced are wheat, corn, oats, hay, potatoes, fruits, vegetables, etc.; the soil is slate, and there are iron mines here; the Shenandoah Valley is not subject to droughts, and we have no malaria; all kinds of small fruits do first rate here; thousands of cattle, hogs and chickens are raised here, and are shipped to Baltimore, Washington Philadelphia and New York; the best of butter, cream and cheese are produced here; bees obtain surplus here from March to November, and our honey is marketed in Winchester, Washington, Baltimore, Philadelphia and *at home*, and sells at from 20 to 25 cents per pound.

Advertisements intended for the **BEE JOURNAL** must reach this office by Saturday of the previous week.

Rural New Yorker.

The Influence of Food.

PROF. A. J. COOK.

We often hear farmers remark that food has more to do with fine stock than does pedigree. While we do not think this is true, yet we must confess that good feeding is no mean factor in successful stock breeding. Long and careful breeding, indexed by a valuable pedigree, insures susceptibility, which makes great results possible, but only with proper care. A 50-horse power engine possesses great potency, but on one-fourth rations of fuel it would accomplish less than a 10-horse power. Yet it would be foolish to argue that fuel was more important than the style of the engine.

Among higher animals we have no evidence that food produces rapid structural changes. Food, selection and time will change the form, carcass, and even the habits, but only after long years of modification. Among lower animals we have some startling facts that show most graphically that food is sometimes a most powerful agent, able to effect a radical structural change in a very brief time. We all know that, in the main, the animal functions are very similar, even though studied in animals which are structurally wide apart. The now generally accepted philosophy that all animals have a common ancestry should lead us to give wise consideration to the peculiarities of lower animals, even in our treatment of the higher forms. If, then, we can show that food is potent to substantially modify the entire organism and life habits of bees, it should serve to exalt our estimate of its value and influence as affecting the higher animals. The same egg may, yea will, produce either a worker bee or a queen, the character of the progeny depending solely upon the character and quantity of the food consumed. If the food is rich and abundant the result is a queen bee. If it is less nourishing and stinted in quantity, a worker bee is the result. Even after the egg hatches, the young larva may be fed for three days in the meager way, then fed the richer food in ample supply, and a queen will result, though not so valuable a one as though fed the rich royal pabulum in generous quantities from the first.

Now, let us see what the changes are that are wrought by these improved good rations. The queen is longer and slimmer than the worker bees, and her ovaries are feebly developed, capable of growing daily from 2,000 to 3,000 eggs. On the other hand, there is a more feeble development of such organs as are used in procuring food and performing the various operations of the hive. Thus the queen has no pollen baskets, her

jaws, as compared with those of the workers, are weak, her tongue short, and her glandular system and stomach are more fully developed. Thus a simple modification of the food regimen produces sterility in the workers, which are only sterile females, while the organs that are more intimately connected with nutrition are more strongly developed. It would seem that the food is too slight to stimulate the growth of the ovaries, which is appropriated in a more decided development of the special organs which minister to nutrition. If food can do all this with bees, it certainly may be regarded as a very important element in the development and care of our higher animals.

For the American Bee Journal.

Racks for Surplus Honey.

J. W. PORTER.

I notice some attempts are still being made to get over the difficulty I successfully accomplished years ago, and my plan was illustrated on page 240 of the BEE JOURNAL for 1878. Mr. Whitford's plan on page 56, I see is referred to by Mr. Heddon on page 95.

The purpose was to have a case that would be bee tight; one that could be readily tiered up (a point of great value here), and one that would hold the sections lengthwise of the hive (no other would do for me), and come right down on to the brood combs, with only bee space between sections and brood; one, too, that would admit of long separators of wood. All

Rack for Surplus Honey.

of these points are attained, and the continued use of this rack, for years, have been so satisfactory, that I think a real service will be done to republish the cut of it. It was freely contributed to the fraternity. I had experimented much, and have seen nearly all, including Mr. Heddon's latest; which, while it has some valuable points, is open to serious objections. Mr. Whitford's mistake is in making his T supports solid. Made of X or XX tin, and so bent as to have them thus  standing $\frac{5}{8}$ inch high, all the strength needed is obtained, and the space permits them to rest on a nail inserted at the apex.

Mr. Heddon asks about bee space. The tin angles are flush with the bottom of the case, and the case rests on strips $\frac{7}{8}$ wide, by $\frac{3}{8}$ thick, placed one at each end, transversely across the brood frames, tight to the ends of the hive. Now, with this arrangement it matters not if the bees build wax bridges in bee space, prying between the case and transverse stick, separ-

ates all without displacing or lifting a comb below. They can be made to fit any hive. At one time I considered it a good advantage to use the deep, wide frame, with hanging separators, and with some bees. Much more can be done with them than with any case. Because of their use in Langstroth frames, I adopted the size of $4\frac{1}{2} \times 5\frac{3}{4} \times 2$ sections; six just fill the frame.

My cases are made to take 18 of them. The separators are notched to let down in the middle tins to bee depth. Five separators only to 18 sections, and each one movable, and of wood or tin may be used. I much prefer wood.

The T should be stamped not hammered. That is done by slitting an oak or hard wood block, strips of tin, $1\frac{7}{8}$ inches wide, are cut and bent slightly into the slot. Then reversed and forced by a lever into the next slot, and they are finished in the shape of this U. An iron or steel square blade of equal thickness is used under the lever. Tinsmiths can form them, but false bends damage the strength greatly.

Charlottesville, Va., Feb., 17, 1883.

Translated from Bienenvater by A. R. Kohnke.

Wax—Tests for Proving its Purity.

PROF. P. F. RESCH, S. J.

What is wax? To the uninitiated this may seem a very superfluous question; but the fact that there are a number of natural products going by that name, demands accurate determination of the kind. For instance, in some churches the ritual directions are to use wax candles at certain ceremonies; the ordinance also specifies of what kind of wax such candles must be made, viz.: "beeswax;" but that is as far as the ordinance specifies. Hence, it is customary to use the product of the native bee, in the different countries where such candles are used; in Europe, it is the common or German bee, or the Italian; in Syria, the Syrian; in Cyprus, the Cyprian; in the East Indies, *Apis dorsata*, *florea*, *Indica*; in South America, the species *Gothuir*, *Melipona*, which furnish the wax. It appears that the wax from all the different species of bees possesses the same chemical and physical properties.

For the sake of convenience it has been found necessary to classify wax under the following heads: Beeswax, vegetable wax, and animal wax. On comparing the elementary constituents of the different kinds, we find them to be composed of carbon (C), hydrogen (H), and oxygen (O) in the following average proportions:

Beeswax... C, 81.70, H, 13.26, O, 5.04
Veg. wax... C, 74.61, H, 12.38, O, 16.01
Min. wax... C, 85.70, H, 14.30, O, 00.00

As beeswax, to a great extent, is adulterated, the description of a few handy tests may not come amiss.

Pure beeswax has the following properties: At 30° C. it may be kneaded; between 69° and 70° C. it melts. Its specific gravity is between 0.960, 0.969. A higher or lower spe-

cilic gravity indicate adulterations with foreign substances.

Pure wax, when melted, appears as a clear, slightly yellow liquid, and, if put into hot water, should not dissolve the same, nor leave any sediment. This is one of the most important tests, and in order to better observe changes of transparency, or a sediment, should be made in a test tube. But it does not follow that the wax is pure, if no discolored water or sediment is noticed; hence, we have to apply other tests.

Take a piece of caustic lime and slack it in about four times its bulk of water. After it has well slacked, and been well stirred, it must be filtered through filter paper, using a glass funnel for this purpose. Of the now clear lime water obtained, add some to the still molten wax, stirring it well all the time. If now the water becomes whitish or cloudy, or even a sediment is noticed, it indicates adulteration by stearic acid, which combines with the lime, forming an insoluble precipitate of stearate of lime.

A still more delicate test may be performed by dissolving some of the wax in ten times its weight of chloroform, and then adding some of the clear lime solution.

The above are the principal tests. To detect other impurities, which are added to increase the weight and bulk of the wax, but do not combine with it, will not be difficult, and will show themselves by melting the wax. The following substances have been found to be added, to increase the weight: Water, starch, phosphate of lime, sulphate of lime, carbonate of lime, ochre and sawdust.

To adulterate wax the following ingredients are used: Stearine, paraffine, tallow, ceresine (or ozokerit), galipot, and vegetable wax.

To detect water, it is necessary to submit quite a large quantity of the wax to the test of melting, and keeping it at the boiling point, for sometime, to evaporate the water, without burning the wax, of course. Any decrease in weight indicates an admixture of water, the amount of which may be determined by the scales. In the same manner, viz.: by melting, other impurities may be detected, as most, or all of them, will be found as a sediment, either in the wax on the side next to the water, or will even sink entirely to the bottom.

Tallow causes wax to feel fatty or greasy to the touch. One cannot write on such wax with a piece of chalk, while on pure wax it can be done. A little piece of such adulterated wax thrown on a red hot stove, or other iron or burning coals, will emit a heavy, very disagreeably-smelling smoke.

For paraffine, the test is as follows: Take a small piece of the wax, put it into a watch glass, and pour sulphuric acid on. Pure beeswax will be charred, and the paraffine remain without being changed. The same test is applicable with reference to any kind of mineral wax, as ozokerit or ceresine.

If pure wax is put into either, about

half of it will be dissolved, whilst vegetable and mineral wax is entirely soluble in it; with this difference, that the latter, in part, forms jelly flakes. If wax, on being dissolved in either, loses more than half, it contains either vegetable or mineral wax. Youngstown, O.

For the American Bee Journal

Spring Management of Bees.

FAYETTE LEE.

I am located 60 miles west of St. Paul, on the Manitoba railroad. I have been in the bee business six years; the average yield, per colony, spring count, is 92 pounds. Our surplus honey is from basswood and golden rod. I do not claim that the way I manage bees is perfect, but by putting our experiences together we can learn something. When I first began keeping bees, I borrowed all the bee papers I could find, besides subscribing for three others.

I use a two-story hive with a loose bottom-board. I believe they are the best. I use the American hive, nine frames in each story. Early in April, I put the bees on their summer stands, and raised up every hive and cleaned the dead bees from the bottom board, and closed the entrances half an inch. The next thing is to know if they have honey. I take off the cover and roll back the quilt; if they have capped honey in sight, I close the hive and mark it: "honey for ten days." All hives not having honey in sight, I mark, "short of honey." Beginners should not open a hive when bees need feeding, and tear out all of the frames to see the queen, or ascertain if they have brood. The way I handle weak colonies is: I only take out one frame of comb, just as close to the brood as possible, and in its place I put a frame of honey from some heavy hive, or fill a comb with honey, or syrup made from sugar.

Careless handling is the cause of weak colonies swarming out in early spring; you disturb the bees and queen by handling the brood combs too much; it causes robbing, and out they go, to be killed by trying to enter other hives; tuck them up, warm, till there is plenty of honey and pollen coming in, and then it will do no harm to handle the combs, or look for the queen. I get all the brood possible by the time that fruit and dandelions bloom: by spreading the brood in strong colonies, and taking out now and then a frame of brood, to build up the weak ones. The best moth-trap is a few young turkeys or a pair of ducks; try them and see. As the bees get strong, give them wider entrances; it will not pay to unite weak colonies in early spring; do not think, because they are weak, that the queen is poor; give them brood and bees, and you will see plenty of eggs in a short time.

Early in May I want every hive full of brood, in order to get a large yield of honey from every hive, and a good

increase. I want nine frames of brood in every hive by May 25; and the way to get it done is by spreading the brood combs. I take the outside comb and put it in the centre of the brood-nest; I do this every seven days, until I get nine full of brood. I handle the brood very carefully. In April I have all hives full of brood. If honey is coming in, I get some swarms in May and June, but more in July. I put on the top-story as early as June 1. I have surplus combs in the top story, from the last season, and what I lack is filled by frames of foundation. The increase that gives me the most honey is one swarm from two. I put one frame of brood in the upper story, when I put it on; this causes the bees to go up there to work. I save the queen-cells from the first colony that gives a swarm. In seven days after, I take out all but one frame, and make as many nuclei as I have cells, and take two frames of brood and put with them from other hives. I do this every six days until they are full of brood; as fast as they swarm I return them to their own hive, and take three frames of brood from them, give them a new location, put the three frames of brood in an empty hive, and put it on the old stand. In this way I keep all strong colonies by adding brood. I do not like too much swarming in July; it spoils the honey harvest. By returning them, giving them a new location, and removing some brood, I keep them just where they will give us a large yield of honey. June swarms always pay me best. A swarm will fill its hive with comb in two weeks in June.

For the American Bee Journal.

Are Half-Pound Sections Desirable?

E. N. WOOD.

As much has been said about the size of sections, I have taken some pains to find out how our bee-keeping friends felt about the matter, in this section of the country, and I have not heard from one that favors the half-pound section, from parties that have a home market for all their product. We all ought to strive to hold to the present sizes of boxes and hives, as changes mean great expense and trouble. It seems to me that a general change in the size of honey boxes will soon bring new styles of hives that will be supposed to be better adapted to the use of the new box, and these new styles will catch many who are young in the pursuit, and as first impressions are strong, many of them would never change; many more sizes would be added to our now standard sizes of hives, frames and boxes. There are four general or standard sizes of boxes, $4\frac{1}{4} \times 4\frac{1}{4}$, $5\frac{1}{2} \times 5\frac{1}{4}$, $5\frac{1}{2} \times 5\frac{1}{2}$, $5\frac{1}{4} \times 6\frac{1}{4}$. The few sizes of boxes now in use has enabled the manufacturers to bring the prices down to the present very low rates, as they make large quantities of each size at a time, whereas, if the half-pound section comes into general use, I think the

prices of them all would be somewhat higher than at present; for get the craze (if I may so call it) once started and it will sweep over the country, and nearly every bee-keeper, no matter what the size his hive may be, will think he must come to the half-pound section as near as possible, and there would be as many sizes of half-pound boxes as there are different sizes of hives at present, and I fear more, as some would reduce their boxes in one way and some in another.

I think, perhaps, for a season or so, the half-pound sections may take well in the market, it being new, and somewhat of a novelty, but it will become a drug upon the market and be driven out of use, to the sorrow of those that have made expensive changes.

Again, I think one-pound is as small a quantity as most people want to buy. It is about the right size to put upon a plate without cutting in two, and if a pound or more of honey is to be bought they would certainly pass by the half-pound lots (for they have the appearance of too much tare) to the 1, 1½ and 2-pound boxes, and, again, I am afraid we cannot get near as large a yield per hive with these small boxes. Let us hear something of this from those that have used them.

North Lansing, Mich.

For the American Bee Journal.

Queens Reared in the South.

THOS. C. DAVIES.

On page 182 of the JOURNAL for April 4, Mr. T. S. Johnson, of Bogart, O., asks Mr. G. M. Doolittle and "any others who have had experience with Southern queens, if he thinks bees from a queen reared in the South are as hardy and well able to stand the long, cold winters of the North, as those from a queen reared here?" Being one of the "others" who have had some experience with Southern queens, I would like to give the following details:

In April of last year I received a dollar-queen from a Southern breeder, and in a few weeks after, a selected tested queen from the same person. I also received a selected tested queen, and a Syrian queen from a New York breeder. From those two selected queens, several fine queens were reared during July and August, and when preparing my bees for the winter, my queens were as follows: Two from the South, two from the State of New York, and 24 reared at home. Several of those were reared the season before the last, and one of them was reared in July, 1879. She had been such an excellent queen, that I had not courage enough to kill her last fall, and she was allowed to live as long as she could. About three weeks ago she died, I suppose of old age.

Twenty of those, including the two from the South, and the selected one from New York, were wintered on their summer stands, well packed in chaff. On April 3, they were all examined, and the two from the South

had their hives well stocked with bees and brood, and fully equal to the one from New York. In fact, those 20 colonies, except one, have wintered admirably, and they are now so equal that I cannot tell which of them is the best.

Of the 8 in the cellar, 6 came through well, but the other two are rather weak, and queenless. One of the queens died last week, and the other, three weeks ago. I united these two, and have sent to the Southern breeder, four days ago, for a queen to give them.

I do not know what has been the experience of others with Southern queens, except that of Mr. Doolittle's with his Texan queen, but I must say that I am well pleased with them so far. I believe with Mr. Doolittle, that "there is a difference in bees about wintering," but can hardly believe, at present, that it is due to the part of the country where they are reared. I sincerely hope that the bee-masters, by "studying and experimenting," will succeed in getting more light on this inequality of different colonies regarding wintering, before another cold winter comes.

Pittsburgh, Pa., April 11, 1883.

For the American Bee Journal.

Bee-Keeping in Florida.

C. H. LAKE.

As many bee-keepers throughout the country are turning their attention to this State, and being in communication with several prominent bee-keepers already located there, through whom I have gathered the information herein contained. I give it, thinking it might be of service to those about to locate there. For the past three years I have been thinking of removing there permanently, owing to the fact I am of a consumptive family, and suffer extremely with lung difficulty, especially in cold winters in this latitude.

There is a belt of country along the east coast, rightly termed the "Bee Belt." Ten years ago bee-keeping was an unknown industry there, and scarcely a dozen colonies could be found among the few families who then inhabited that portion of Florida. This "belt" commences about opposite Port Orange, extending South as far as Oak Hill, a distance of 125 miles, or thereabout.

Thousands upon thousands of acres of marsh are there covered with the black mangrove, the best and greatest honey producing plant known in Florida. Within this radius the black mangrove predominates, while above the head of Indian river, the red mangrove grows almost exclusively, which, I believe, is not a honey-producing shrub.

This "belt" offers superior inducements to bee-keepers, and when the fact becomes known, bee men will not be backward in availing themselves of the opportunity, by moving in and locating at favorable points. From recent letters from Mr. O. Olson, of New Smyrna, who is, with-

out doubt, the most experienced and successful apiarist in Florida, making bee-keeping his exclusive business, he informs me that it is "impossible to overstock the country." Mr. Olson makes the study of honey-producing flowers a portion of his business, and from "careful microscopic examination of the flowers of the black mangrove," he finds they contain "one-fourth of a drop of honey." When it is taken into consideration that this shrub bears thousands upon thousands of blossoms each season, one can get some idea as to its honey-producing qualities. It is asserted that 90 per cent. of the surplus honey gathered during the season (which lasts usually about ten weeks), is from black mangrove. While there are a great variety of the other honey-producing flowers, blooming at different periods throughout the year, among which can be enumerated the "saw and cabbage palmetto, gullberries, sweet bay, wild sunflowers, yellow jessamine, golden rod, orange bloom, snow vine, basswood, sweet gum, etc., etc." There is no reason why the honey cannot be gathered. With all these natural requisites of building up the colonies to perfection, by the time when the mangrove season opens.

There seems to be a great diversity of opinion among the Florida apiarists in regard to the cabbage palmetto. Some assert that "the bees neither gather honey or pollen from its bloom," while others are equally confident that "it equals in every respect the mangrove, as a honey producer;" while others affirm that "it yields pollen only." Different situations probably accounts for the varied results, like many of our own honey-producing shrubs, trees, etc.

Florida has its disadvantages, like all other great honey-producing States, and will, till the tide of immigration is sufficient to establish railroads and water conveyances. New Smyrna is 125 miles from the nearest express office, and for transportation the inhabitants have to "depend on schooners along the coast." A small steamer has been put on between Jacksonville and New Smyrna, for the winter, but is taken off in the spring; this steamer makes one trip a week, but all this will be removed as soon as business springs up, and the country becomes more settled.

Besides "being out of the world," we have the bear, dragon fly, several bee birds, and scores of other enemies to the bee to contend with, and, for that reason alone, we wish the entire country was settled up, while the bee moth reigns supreme, which is owing to the fact that what bees were kept by the old inhabitants, were in the old "gum or moth harbor."

A few more interesting items may not be amiss. W. S. Hart, of Hawks Park, has nearly 100 colonies of bees, and has the best out-fit, consisting of the improved machinery for carrying on the business, foundation machine, evaporating machinery, etc., that there is in Florida.

A. J. Packwood has started with 20

colonies, and has, during last season, taken several thousand lbs. of honey.

H. Olson and Mr. Wilson, from Ohio, seven miles south of New Smyrna, have 184 colonies, the largest apiary in Florida. They make bee-keeping their sole occupation, and are supplied with machinery for the manufacture of hives and everything pertaining to them, and work up an immense amount of lumber during the year. Their bees are mostly Italians, with some hybrids and a few blacks. This seasons crop foots up 25,800 pounds of the best honey we ever sampled.

In regard to the quality of Florida honey, Mr. C. F. Muth, of Cincinnati, who has handled most of the crop produced by these gentlemen, says "he considers their honey the finest ever placed on the market, and that it sells more readily than the white clover honey of the North."

L. H. Bivens, of Glencoe, has 37 colonies, and has shipped, this year, 2,000 pounds. M. B. Rolfe, also of Glencoe, has 8, which has produced 600 pounds.

R. S. Sheldon is one of our oldest bee-keepers. He has, for years past, shipped thousands of pounds of excellent honey, and last year his success was very satisfactory. In the spring he had 53 colonies, increased by artificial swarming to 84, and took thus far, Oct. 1, 6,300 pounds. From a natural swarm hived April 15, 328¹/₂ were taken, up to Aug. 15.

Mr. Morrison Lewis, of New Smyrna, is the pioneer in bee-keeping in Florida; that is, he was the first to make bee-keeping pay. He commenced in 1868 with one wild swarm, which he found in the woods, which did finely, increasing to several colonies, besides producing a large amount of honey, the second year, which showed Mr. L. what they were capable of doing, when properly cared for. He received 25 to 30 cents per pound for all his honey, for some eight years. He introduced the first movable comb hive and the first honey extractor into the State, and shipped the first barrel of honey, gathered in Florida, to New York, in 1876. From his 30 colonies, he has shipped, up to Oct. 1, 1882, over 3,000 pounds.

From a private letter received recently from Mr. O. Olson, he states: "I made six swarms from one colony, this season, and took from the old colony 440 pounds of extracted honey. I have, at last, found a climate where I like to stay, in spite of all the insects, which is a great drawback on this coast during June, July and August. A more pleasant and healthy climate cannot be found on earth, and I have lived in Europe and several of the States of America. Smyrna is a place of twelve families, and six miles distant, are twelve more."

I could continue this article to a greater length, but have given the important information sought after by those thinking of going into the business, in Florida. Any further information will be cheerfully given as far as in my power, or by addressing any of the above named gentlemen.

Baltimore, Md., Feb. 12, 1883.

For the American Bee Journal.

Experienced Students of Apiculture.

JESSE OREN.

I cannot see the force of the objections made by Mr. Heddon, page 73, against the views advanced by Dr. Besse in his "advanced step," in recommending diplomas to be given by the North American Apiarian College. It seems to me that Dr. Besse requires of the applicant for honors all that Mr. Heddon requires, and a little more. Mr. Heddon's diploma and "red tape circumlocution," as he calls it, would pass current with the society, and entitle the young man to an examination. Dr. Besse demands an experience of one year in all the manipulations of the apiary. Mr. Heddon, five months, or a bee year, if you please so to call it. Both men are on the same plane in this period of preparation. If Mr. Heddon was one of the examining committee, as he probably would be, and his line of students, with their "red tape," signed "Get there Success," should file into line before the committee, would he not approve them? Would he protest against Dr. Miller's, Doolittle's, Dadant's, Jones', Dr. Besse's, Grimm's "Get there Success?" We believe he would admit all the names to his *ad eundem* list of red tape. They are all well known to the bee world. I am glad they are known, and that they have spoken out. Red tape from any of them would pass a young man into my yard. Still I should prefer the combined red tape of all as being better than of any one alone. One might be all extracted, the other all comb, and half-pound sections at that, too. I might be suited with a mixed husbandry.

Some men are born poets, and must sing; others are born mutes, and cannot sing. There is this difference, also, among bee men. Some few miles from me lives a man who has been "getting there annually" with his 15,000 to 2,000 pounds of honey. He is a local phenomenon, and only known at home. His name is "Get there Success;" but the North American Society knows nothing of him. He has paid \$100 per month for an apiarian assistant; and any red tape he should adopt would pass the owner into my yard as competent. We do not want a private monopoly of red tape, but rather, a good supply from every part of the country. In this way, many who are mutes, will come out of their holes and hold up their hands to be seen.

We hold that red tape does mean something; and that if Mr. Heddon has any, he is proud of it, and would not readily part with it. A graduate of Yale or of Ann Arbor does not imply an illiterate person by any means, but, on the contrary, such graduation is *prima facie* evidence of scholarship, the United States over. We do not expect to make such men as Sir Isaac Newton, Kepler and Leverrier by diplomas, nor, perhaps, such apiarist as Mr. Heddon either; yet this admission does not diminish the significance of diplomas. We are friendly

to Dr. Besse's "advance step," and believe the Society will so look upon the matter, when it meets in Toronto, next autumn. I have just given Mr. Heddon's and Mr. Jones' address to a young man who wishes to learn our business. I have given him a hope that he may be able to meet us at Toronto and pass examination next autumn. With the hope of success, he is going to work the ensuing summer. But like many lawyers and doctors, he may graduate and afterwards make an honorable living hauling manure and digging potatoes.

La Porte City, Iowa.

Haldimand Bee-Keepers' Association

The Haldimand Bee-Keepers' Association held its third meeting on Saturday, March 31, at Nelles' Corners, Ontario, pursuant to adjournment.

Members present, E. DeCew, President; and Messrs. James Armstrong, R. Buckley, Robt. Coverdale, Ephraim Gee, Wm. Abbott, Joseph Carter, Fred. Mehenbacher, E. C. Campbell, R. Anguish, Ambrose Gloyd, James Gloyd, William Harrison, A. Vanderburgh, Wm. Kindree, David Byers, Henry Smith, Elijah Kindree, R. W. Beam, David Anguish.

Minutes of previous meeting read and approved.

The president gave a short address, after which the first question was taken up.

Two Story Hives.—Mr. Armstrong said it depended on the depth of frames; if the frames were shallow, two stories were an advantage; if deep, one story or 1¹/₂ stories was about the right thing. Mr. Buckley thought that when extracting, a double story was not necessary.

The Desirable Style of Hive Cover.—The president exhibited one which met with the approval of the members. It was very similar to those now used by D. A. Jones, and is deep enough to allow for a chaff cushion in winter.

Bottom Boards.—Caused considerable discussion. A number of members favoring loose bottoms; others preferring tight bottoms; the majority being in favor of the latter.

Spring Feeding.—The president said the best plan of spring feeding, was that of D. A. Jones, and explained how it should be made. Mr. Byers advocated feeding syrup strained through a cloth; it had worked well. Mr. Vanderburgh thought the best plan of spring feeding was to feed in the fall. Mr. Buckley gave his plan, viz: making a syrup of sugar and flour, pouring it into an empty frame, and putting it in the hive between the cluster. The secretary recommended linseed-cake meal as one of the best substitutes for pollen.

Is it Best that Bees Should Swarm?—Mr. Vanderburgh advocating dividing, as did Messrs. Armstrong and Buckley, and recommended having queens on hand for new colonies. Mr. Kindree thought if the object was to increase, natural swarming was best; if for honey, dividing was best. The

majority gave their opinion in favor of artificial swarming. Messrs. Wm. Kindree and Wm. Abbott gave their plans for securing swarms.

How to Rear Good Queens.—Mr. Armstrong preferred rearing queens in a full colony, on full sized frames, and explained his method at some length.

How to Introduce Queens.—Mr. Armstrong recommended the Peet cage, keeping the queen confined until the bees became reconciled to her. The secretary mentioned the plan adopted by Mr. Simmins, of England, who introduced the queen on a frame of bees, with good success.

How to Secure Comb Honey.—Mr. Buckley advocated the use of metal division-boards and section boxes, in the body of the hive. Mr. Gloyd also spoke in favor of that plan, and said it was recommended by prominent bee-keepers. Mr. Kindree was in favor of section boxes in the upper story, leaving the lower story undisturbed.

Register of Each Hive—Its Value.—The president recommended the use of a register for each hive, so that he could tell the condition of his hives without the trouble of examining them every day.

Books and Periodicals.—The secretary advocated the reading of books and periodicals devoted to bee-culture, and thought no progressive bee-keeper should be without one or more good bee papers. In one number of the AMERICAN BEE JOURNAL he had obtained information worth more than the subscription price for a whole year.

Moved by Mr. Armstrong, seconded by Mr. Campbell, that each bee-keeper give a correct report of the number of colonies kept, and the number of pounds of comb and extracted honey from each colony, and what kind of bees.

It was resolved that the next meeting be held on June 16, at 10 a. m., at Cheapside, Ont.

The following statement will show the losses sustained during the past winter:

	Nov. 1882.	April 1883.
Edmund DeCew,	15	5
Robert Buckley,	38	33
James Armstrong,	32	31
Wm. Harrison,	2	2
Ambrose Gloyd,	16	15
Wm. Jack,	8	4
Joseph Carter,	10	9
Robert Coverdale,	6	5
R. W. Beam,	12	9
Wm. Kindree,	15	11
Henry Smith,	2	2
A. Vanderburgh,	9	9
F. Mehlenbacher,	1	1
David Byers,	13	12
Robert Anguish,	37	25
Ephraim Gee,	1	1
E. C. Campbell,	35	32
David Anguish,	4	3
Daniel Rose,	15	7

E. C. CAMPBELL, Sec.

P. S. By the above table it will be seen that the losses during the past severe winter have not been very high, and was caused principally by want of stores. I took mine out of cellar April 9, having been confined for over five months, without a flight.

Three colonies were dead for want of stores; the rest are in good condition, with the exception of two or three, affected with dysentery.—E. C.

For the American Bee Journal.

Remarks on Various Matters.

J. O. SHEARMAN.

The wintering problem seems to be pretty well worn; but not finally settled yet. My hobby has been packing in chaff, in which way I have been ordinarily successful. I wintered over 100 colonies, last winter and this, without the loss of a colony so far. I had all of my weakest colonies in the cellar, including some that were intended for doubling up; but the weak and strong all seemed to stand, in the cellar, about alike, except a weak one that had the dysentery; an examination showed that they had only uncapped honey left, though they had sealed honey in the fall. Also two nuclei, with reserved queens, starved. The temperature of the cellar was as near to freezing as I could keep it; it was below only once. I found that when the thermometer indicated near 40° (as often advised through the papers), they would become uneasy. I had only 27 in cellar. Those out of doors, packed in chaff, did well, so far, set close to the ground, on a little bed of straw, for under packing. That goes to show that it is not quite sure death.

I once thought that I had a good thing on them, if only they were covered by snow, and said the deeper the snow the better, with a sloping board over the entrance, of course; but now I have got bravely over that. The winter of 1880-81 was our test on that point. Those deep under the snow were very uneasy, while others situated on the south side of a hill, where the wind blew the snow all away from the front of the hives, came out bright, strong and healthy. That was a damp confinement, while, this winter, though snowed under, 2 feet or more, they came out nearly dry, with much better results. My conclusions are that a number of causes may induce dysentery: 1. Extreme changes of temperature, particularly if damp. 2. Thin honey, more especially if soured by changes of temperature. 3. Long confinement, if in conjunction with either or both of the above unfavorable conditions. 4. Undue breeding while confined, or anything that disturbs them while unable to fly.

On the half-pound sections, my advice is to put a variety of packages upon the market, to supply all kinds of customers; the half-pounds are well enough for part of the supply, but if all the honey was put up that way, it would be no higher in price than if all were in one-pound packages. The novelty helps the price at first.

During the past season I increased only from 90 to 107 colonies; though it was a noted season for swarming, for over two months. I did it, partly, by putting one swarm into another hive, from which a swarm had lately

issued, increasing the surplus room; and partly, before they got so feverish, by gradual extension of the brood-chamber; at the same time, giving more surplus room. The hive I use enables me to do the latter more readily, as the back of the brood-chamber is movable, the same as a division-board, and I can set them to work in three old-fashioned boxes, with two brood frames, or use 18 of the same sized boxes on the top of 12 brood frames.

I have run 12 colonies all through an entire season without swarming, increasing them to 18 by division, and giving them plenty of surplus room. That was four years ago, in a fast-swarming season; but it takes too much time for a large stock to increase a little at a time.

I had the above mentioned 12 colonies in a location where they gathered plenty of the red raspberry honey, while it was too wet for them to do much on the white clover. It was of very fine quality and flavor, though not so light in color as the white clover honey.

New Richmond, Mich., Mar. 6, 1883.

For the American Bee Journal.

Water for Bees in Winter.

EUGENE SECOR.

I suppose some of our Southern brethren, who have been basking in the sunshine for two months, and whose bees have been "out to pasture" so long that they have forgotten the past winter, will shrug their shoulders and thank God that they do not live in this borean land, when we tell them that we are just taking our hives to their summer stands. Well, I suppose the South is a delightful place to live in, but I have yet to learn that they accomplish more in any of the departments of industry during their long summers, than we in the North do in our short ones. A small portion of Texas came to the front last year in the production of honey, but year by year, the North supplies our leading honey markets, with as fine a quality as can be found this side of California. So, while we can successfully compete with them in the production of honey, perhaps we ought not to be so modest in discussing the wintering problems, which, undoubtedly is anything but interesting reading to them.

I have, to-day, taken my bees from the cellar, where they have been since Nov. 13. The last flight they had last fall, was on Nov. 10. This is the longest period I have ever kept them confined without a flight. My experience, to-day, seems to indicate that they could have endured a much longer night. I never before saw bees so cross in the spring. They are usually so glad to get out and fly, to void their feces, that they did not attempt to sting; but, to-day, I was compelled to don bee-vail and gloves, and, in spite of both, I am now far from "spring poor." There are no signs of dysentery. They did not "spot" their hives during the

winter, nor anything around the yard, in their sight to-day. My cellar was perfectly dark, without any ventilation, and ranged, in temperature, during the winter, from 32° to 48°, usually standing at about 45°. It was quite dry. From March 1, I have, several times, watered a part of them, a thing that I never practiced before, but it had the effect to keep them more quiet, and many of them were "just booming" to-day.

Now as to the results: One colony had starved to death. Four out of six, that were on the bottom tier, one foot from the cellar bottom, that had not been uncovered since putting in, and that had had no water, were dead. Only in one hive were the combs moldy, and all had sufficient stores. Those colonies which had been watered since March 1, were strong and healthy, and began to rob in less than an hour after having been set out.

Soft maples, willows, cotton woods, and elms are in bloom. The prairie anemones have been out for some days. The past winter has been one of the coldest known since the early settlement of the State. For about nine weeks from the 20th of December, it hardly thawed on the south side of the house, and the mercury hugged the zero point most of the time, occasionally dropping down to call on numbers 35 and 40. And for fully three months it was too cold for even a healthy bee to venture far from the warmth of the cluster. Fruit trees, in many parts of the State, have been injured; though in this locality we have not suffered in that respect. Bees have also wintered usually well. Forest City, Iowa, April 16, 1883.

For the American Bee Journal.
Are Bees Taxable?

JESSE OREN.

MR. EDITOR:—On page 42 of the BEE JOURNAL for 1883, you are asked, "Are bees taxable?" Your answer, as given, is in accordance with the facts; but your conclusion is wrong, viz.: property of value is taxable property in Iowa. The statute of a State fixes and names the kinds of property on which a revenue shall be raised. In Iowa, bees are exempt by statute, and about all your patrons here are anxious that you shall so answer. Of course I know that it is not reasonable to expect you to know the laws, etc., of all the States. I have made this matter a special study years ago, and the matter was determined by the Attorney General about 15 years ago, when a special bill was got up by a member of the Legislature, exempting bees, etc. He said that bees were already exempt. But year after year we put in assessors and boards of supervisors who are ignorant of the law, and who reason that all property ought to bear its share of the public burden—good reasoning—but not Iowa law. But who knows any better than you do that the average assessor's judgment as to the value of a colony of bees on the

first day of January is a very poor judgment. He cannot set true values. Enclosed you will find a spicy digest of the subject written by a lawyer of Black Hawk County, Iowa. He had my assistance in the matter. We must, however, fight the battle over and over, year after year. The question is not, "Should bees be taxed in Iowa?" but, "Are bees taxable under our laws?" Please, hereafter, when asked that question, answer, "Not by the laws of Iowa, etc." The BEE JOURNAL, with that answer, will become notorious property, and will be preserved for the eye of the new assessor.

La Porte City, Iowa, Feb. 5, 1883.

ARE BEES TAXABLE?

MR. EDITOR:—Allow me to ask yourself and readers why it was that the board of supervisors of Black Hawk County, on Friday, Jan. 10, adopted Mr. Jenney's classification of taxable property for the year 1879, without first revising it so as to make it legal? I trust that they acted conscientiously in the matter. But will you please, or will somebody please, explain how and where they got their authority for placing bees upon that list? Perhaps our board did not know that they were exempt from taxation in Iowa? Perhaps they have some authority unknown to outsiders? Will somebody please rise and explain?

Now, Mr. Editor, "let us reason together," and see if we can find a little law which is, and ought to be plain, to every reasonable being, at least after it has been pointed out to them. I believe I can show by statute that bees are as plainly exempt as if they had been written in gilt letters at the head of the chapter of exempt property. First, what are bees? Are they vegetables? Are they minerals? Or, are they animals? To which of these kingdoms do they belong? Of course, you and everybody else will say that they are animals, of the insect order. Now, since they are animals, then, as animals, they are twice exempt under the statute. Exempt from taxation, first, by section 797 and 801 of Code of Iowa, 1873. Section 797, division 4, exempts from taxation "animals not hereafter specified." Section 801 enumerates the animals, viz.: "Horses, cattle, mules, asses, sheep, swine." Now, we see that it does not mention bees, nor does it intend for bees to be listed, or it would have mentioned them. At a glance we can see that to have mentioned all the animals exempt would have been an endless task, and when completed would have been a volume of itself, and only merited our ridicule. It might have read like this, viz.: From the animal kingdom there shall be exempt 20 species of the quadrumania, viz.: The buffalo, the elk, the deer, the cat, the dog, the mouse, etc. Of cetacea species, the oyster, the clam, etc. Of birds, the wren, the robin, the swallow, etc. Of reptiles, the lizard, the garter snake, the bull snake, etc. Of insects—30 species—viz.: The hornet, the wasp, the asp, the bee, the bumble bee, and

so on, *ad infinitum*. But the cobra-copella, the rattlesnake, the grizzly bear, the parrot, the seal, the golden fly of South America, owing to the vast amount of money invested in them for show purposes, shall be listed and taxed at twice their appraised value. Such might have been the form of the section had the Legislature attempted it. But they chose a wiser plan, and only enumerated those animals which were to be taxed, and exempted by section 797 all others—bees with the rest.

Again, according to Langstroth and other standard authority, the average life of a working bee, in summer season, is only six weeks, while it is a mooted question whether any worker ever lives to so great an age as seven months. Now, a bee being an animal, under section 821 (last clause), under "classification of property" for taxation, we find that "no entry shall be made on said books of any animal under the age of one year, except swine." The queen-bee is the only bee which lives to so great an age as one year. Her market value is 75 cents, and thousands are annually sold to A. I. Root, of Medina, O., at that price. We find by this section (821) that bees are again exempt. "Well," say some, "it is not the bee, it is the value." To this we again fall back on section 797, where we find "farm produce harvested within one year previous to the listing thereof," is exempt from taxation; and since all that is valuable in a colony of bees, except the 75 cent queen-bee, is harvested "within a year previous to the listing thereof," and comes in exempt along with thousands of bushels of wheat which the farmer may have in his granary or stack, the thousands, yes millions of dollars worth of wearing apparel, including valuable household furniture, thousands of dollars invested in swine under six months old, calves, colts, chickens, and the like, even down to a \$5,000 shawl, such as Mrs. L.—— is said to wear, and other articles of a wardrobe proportionately expensive. From the list of exempt property, it is plain to be seen that it is not the intent of our law to tax all valuable property, for if it did, why exempt so many millions of valuables? In conclusion I would say that I have not talked with any lawyer, who, after a little reference, did not see the exempt condition of bees under our law. I might refer to Clark & Curtis, of Lemars, Ordway, of Waterloo, Judge Gilchrist, of Vinton, the two law firms in our own city, viz.: Bishop & Sharon and Chas. Bishop, and many others whose names I will not occupy time and space to enumerate.

Now, Mr. Editor, please excuse this space-consuming article, as my object in penning this is to aid in the support of the Constitution of the United States and the laws of the State of Iowa. S. A. O.

[We are very glad to make the correction requested. Certainly, on this showing, in Iowa, bees are *not* taxable property.—ED.]

SELECTIONS FROM OUR LETTER BOX

Are Bees Taxable in Iowa?

Will you please state whether the laws of Iowa exempt bees from taxation? All agree here that if bees are animals they are then exempt. Some think they are insects.

PETER S. TRIEM.

Mt. Auburn, Iowa.

[We are informed that the Attorney General, some 15 years ago, decided that in Iowa bees are not taxable, and according to the laws of that State, they are not assessable. Apiarists in Iowa should show this to the new assessors.—Ed.]

Honey Flow in Louisiana.

There has been a fine flow of honey; the bees are in splendid condition. I have been running for increase, and yet from 100 colonies I have taken 3,500 pounds of good honey. I shall start for the North about April 25, with a lot of colonies.

E. T. FLANAGAN.

Kenner, La., April 16, 1883.

A Beginner's Experience.

My father kept bees as long ago as I can remember, and I was always fond of them. About 5 years ago, I and a neighbor procured about a dozen each, and as we had heard of the new way of dividing, we divided them again and again, expecting to get rich in that way, but the winter cleaned us out of the bee business. Taking the advice of a friend, I subscribed for the BEE JOURNAL and bought Cook's Manual, and concluded to try again, after learning more about bees. I sold enough honey to pay for my bees, and all that I had ever spent on them, and still have the bees left. They are in good condition now, and will be ready for the harvest when it comes.

Casey, Ill. D. R. ROSEBROUGH.

Wintering Bees, etc.

As dry sawdust is hard to get in the fall, I procured it dry, after harvest, and had plenty in the fall. I have tried chaff with success, but do not want it any more; it harbors mice, and gets damp very quickly. I must either clip the queen's wings or run a great risk of my neck, so I choose the former. I like a deeper frame than the Langstroth, for Canada. I want my frames crosswise; I think a division-board as needful as the hives. I use an outside box about 6 inches larger than the hive, with the entrance bridged, and packed around and on top (with movable side), pressed tight on sawdust. In frosty mornings, in the fall, I remove all outside combs, which can be done very fast, and feed up, on from 5 to 7 frames. Where do bees cluster in the fall and winter? Below the honey; the only

place for them, and just where they should, to give heat for sealing; they have warm honey all winter. I have yet to lose the first good colony prepared in the above manner. I have no carrying to do, in the spring, and bees are packed all the spring, and are not coaxed out, with every sunbeam, to get lost. Two colonies starved, in Langstroth hives, with honey in the hive; sometimes bees cluster in the centre, and getting to the end of the frames in a cold spell, they will starve with honey at the other end. Some of my bees have not flown for 147 days; neither do they seem to want to. They are in excellent condition, with about 5 inches of sawdust on the top. For such a terrible winter, bees that are packed have wintered well. My experience will not agree with that of Prof. Cook, as stated on page 85 of his Manual. In every case, with me, the field bees have decided what shall be done. Last summer I found them keeping the queen from drone cells, and even using violence to stop her from laying drone eggs. I learn from them as to whether there should be a second swarm or not.

CHAS. MITCHELL.

Molesworth, Ont., April 9, 1883.

Willows for Pollen.

I send a shoot taken from a bush or tree, for identification. I find it literally covered with bees, for the sake of the profusion of its pollen. I can liken their labors upon it to nothing else except what we have all witnessed at the rye meal basket. I take it to be a species of the willow, of which Dr. Barrett (1830) enumerated 100 species growing in North America.

WM. S. BARCLAY.

Beaver, Pa., April 17, 1883.

[It is one of the willow family, as you have surmized.—Ed.]

My Experience With Bees.

I have had bees for more than 30 years, but never paid much attention to them until the spring of 1879, when I concluded to give them my attention (having quit active business), and to that end, I procured a book on the subject, read the science up, and thought I was master of the situation. Having 5 colonies of black bees I divided them according to instructions in King's Text Book, and succeeded beyond my expectations; in the fall I found myself possessed of 10 colonies in good condition for winter, and got some surplus honey. I put them in the cellar, and they came out all right in the spring of 1880. I again divided and had 20 in the fall, and got a small amount of surplus; all being heavy and in good condition for winter. I thought I would try out-door packing, and packed 10 in oat straw and chaff (after Mr. Heddon's plan), and 10 put in the cellar. March being so pleasant I set them all out, and unpacked those that were out, all being in good condition, so far as I could see; but April and part of May being wet, cold and windy, they commenced to die off very rapidly, leaving nice clean combs full of honey, so

by the middle of May I had but one weak colony left, which died in the fall, after all my nursing. With over 100 frames full, or partly full of honey, I concluded to try it again, and bought 12 colonies, part hybrids and part blacks, and got one colony from Mr. King, of New York. Increased them to 26, and got 335 lbs. of box honey, which I sold at 20 cents per pound, which paid for the 12 colonies bought. I put them away for the winter, packed in the summer stands, as before, all in good condition. They came out in the spring of 1882 without the loss of a single colony. Expecting big things, I bought \$47 worth of supplies, and increased my stock to 48, by my former method a little modified. Upon examination Oct. 1, I found them nearly all short of winter stores, some not having 5 lbs. of honey, and I got no surplus, except from one colony, and that gave me about 25 lbs. of inferior honey. I did not like to see them die, if I could help it, so I bought two barrels of coffee A sugar, and made it into syrup and fed them, so they averaged in weight from 18 to 30 lbs. I have packed them in planter shavings. I suppose there never was a worse season for honey in our county before.

WM. B. MCCORMICK.

Uniontown, Pa.

Queen Nursery, Observing Hives, Etc.

Please answer the following questions in the BEE JOURNAL:

1. Seeing that queen nurseries are required for the purpose of having a supply on all occasions when needed, and few bees can be spared for such nurseries, how are they to be protected through the winter; it being necessary to have them strong to keep up heat for winter protection? As high a temperature being as necessary for a weak colony as a strong one, and the natural heat will not be sufficient, how is more heat to be created? I have never seen anything giving instructions on this subject, although Prof. Cook so strongly urges rearing queens.

2. In the observatory hive, as described by Prof. Cook, page 113 of the present volume of the BEE JOURNAL, which, of course, is intended to be in the house, study, or some such place, should not the alighting board be at an open window, for the egress and ingress of the bees, to prevent them coming into the room, where it is desired to see them? I suppose that, during the winter season, the observatory hive may become a queen nursery.

3. What plan must be taken to stimulate late breeding, as urged in Cook's Manual? He gives the advice, but not the information which is necessary to many; in fact to all who have not had the experience in that way. If the bees have plenty of honey, is there something else better for that purpose?

EDWARD MOORE.

Barrie, Ont.

[Prof. Cook replies to the above questions as follows:—Ed.]

1. I suppose Mr. Moore means by queen nurseries the small colonies or

nuclei in which the queens are reared. Judge Andrews, of Texas, says queens can be kept caged indefinitely by putting the cage in strong colonies. He says even though the other colonies have queens, the bees will always feed the caged queens. Mr. Alley says in his book, the queens may be thus caged for long weeks, but that there must be feed in the cage; that the bees will not feed them. I have always kept the queens in the small hives or nuclei. By exchanging combs frequently, giving empty cells, the queens are kept active. With a good cellar nuclei can be kept over winter as well as full colonies. The chamber containing them must be small; either a small hive, or, better, the regular hive, with brood-chamber contracted by use of a division board. My brother has kept several nuclei in his cellar the past winter. All but one came through strong. That died of starvation.

2. My observing hive is on a board just outside the window. It is just high enough to be convenient. By lowering the upper sash I can lean on it and study the bees for hours without fatigue. My window is a dormer, so it shades the bees in summer and protects them from storms.

2. I think stimulative feeding is fully described in my Manual. We only need to feed a half pint a day, by the use of any of the feeders described. I think the Smith feeder, illustrated and described in my new Manual (just out) is the best.—A. J. COOK.

The Season in Georgia.

Spring has fairly opened with us at last, but bees are in a backward condition. February was mild and pleasant, and breeding progressed rapidly, March set in cold, and continued so with wet and inclement weather all through. Bees could do nothing, but dwindled fearfully: so by the 1st of April colonies, on an average, were not in as good condition as they were the last of February. Box hive beekeepers have lost heavily.

J. P. H. BROWN.

Augusta, Ga., April 20, 1883.

How to Press and Mount Flowers.

In the Michigan State Fair premium list (apiarian department) is offered a premium for the best collection of honey-bearing plants pressed and mounted, or in bloom. Will some one who knows please tell the readers of the BEE JOURNAL how to press and mount flowers?

W. Z. HUTCHINSON.

Rogersville, Mich.

Bees Still in Winter Quarters.

In the spring of 1881, I had 4 weak colonies, and 2 queenless; they increased to 10, and 1 nucleus, tall count; all were packed in chaff. The spring count of 1882, was 9, and 2 queenless. I had from them 500 lbs. of comb honey, and increased to 28; they were all packed in dry goods boxes, with clover chaff. The spring count of 1883, is 27 in splendid condition; I lost one, caused by old bees

and dysentery. My bees are still packed; I expect to leave them so until about May 1, or until the weather becomes settled and warm. My bees are all Cyprians, Italians, and albinos, and I am well pleased with them. I use the A. G. Hill hive, and think it a good one. We have some old fogies here, who keep bees in box hives and brimstone them, etc., and some of them have lost heavily this winter. I could not do without the BEE JOURNAL.

H. HANCE.

Byron, O., April 16, 1883.

Bees All Right.

I have just unpacked my bees, and find nearly all in booming condition. My loss for the winter has been light. I packed, in my usual way, 165 colonies, and, to-day, I find 160 in good condition. Never did I ever see bees in better condition than mine now are. The hives are nearly full of bees, and in some I find brood in four and five frames, with capped drone brood. The weather has been fine for nearly three weeks. I anticipate a fine crop of honey. The white clover has never looked more promising than it does this spring. Success to the Weekly BEE JOURNAL.

L. J. DIEHL.

Butler, Ind., April 17, 1883.

North Carolina Bloom.

Apples are in full bloom, and clover soon will be. I lost 15 out of 100 colonies, last winter. My bees are very strong at this time, and promise great things, if we have a good season.

J. W. HINSDALE.

Raleigh, N. C., April 13, 1883.

Bees are Just Booming.

I wintered 42 colonies in the cellar, of which I lost 1; of 19 wintered on the summer stands, packed with sawdust, I lost none; leaving me 60 out of 61 colonies. I put them into winter quarters on Nov. 15, and removed them from the cellar, April 10, making about 145 days in the cellar without a flight. There is but little spotting of the hives; all are in fine condition and strong, excepting about 6 which are a little weak, but still are from fair to good colonies. All are gathering natural pollen, to-day, from willows and soft maples, the first this season. The thermometer indicates from 78° to 82°, and it is raising quite briskly this evening, at 8 o'clock.

U. E. DODGE.

Fredonia, N. Y., April 15, 1883.

How to use Bee Papers.

I think the printers have scarcely followed "copy," or I have made a strange blunder in my communication, published in the BEE JOURNAL, March 28, page 166, third paragraph. I intended to have written: "Any man who cannot make his business pay for a good journal published in the interest of that business, had better quit the business, etc.," or words to that effect. It now, however, reads: "Any man who cannot make his business pay had better quit the business, etc." You will at once

see the difference. The latter quotation, I presume, goes without asking by the necessities of the case, and does not need a special communication to state it, but while the former may be equally as true, yet it is so often in practice ignored as to need a reminder.

R. J. KENDALL.

Austin, Texas, March 30, 1883.

[It was printed as written in the copy.—ED.]

Bees Confined 159 Days.

On page 180, Mr. McKay says who can beat 130 days without a flight? Well, I can. My bees have been in the cellar 159 days without a flight, and have some 10 days more to remain, at least. All answered to the roll call to-day, "21 in number;" loss, thus far, none. The dead on the floor can all be put into a two-quart measure. The above success is due, in a great measure, to the AMERICAN BEE JOURNAL, of which I have been a constant and interested reader for three years, and never expect to do without it as long as I keep bees. I use chaff mats, and am a strong believer in cellar wintering.

D. L. HERRICK.

Brattleboro, Vt., April 15, 1883.

A Swarm Went to the Woods.

I had 4 colonies of bees in boxes and barrels. Three of them I transferred more than a month ago, in the ordinary way. The boxes broke, and induced robbing, and I had so much trouble that I determined I would let the fourth wait and swarm. But seeing Mr. Heddon's plan, I concluded to try it, especially as the weather was warm, apples, clover, etc., blooming, and several colonies of my neighbor's bees had swarmed during the last few days. I very soon drove the bees into the hive filled with comb foundation; they remained several hours, and took their departure to the woods. I hope others may profit by my experience.

A SUBSCRIBER.

Omega, La.

Stinging and Dislike of Bees.

The bees have a natural dislike to me; they come for me quickly, even when walking in the yard, but not at work with them. One sting will sometimes almost cause me to faint. The rule, that the more a person gets stung, the less it hurts, does not hold good with me; the pain is as severe as it was five years ago. I wear veil and gloves, and have a Bingham smoker, but I get stung often. To allay the pain, after the sting, wet clay is the best thing I have ever tried. The best antidote I have ever tried is whisky; two teaspoonsful before I go to work with the bees. I am not used to whisky, and do not want to be; I hate it. Will some of the readers of the JOURNAL tell me what, if anything, I can put on my clothes to pacify them; and what is the best antidote besides whisky, and oblige one who cannot follow hard labor, and do not want to throw away what it has taken 15 years to learn.

Riverton, Iowa. J. H. STEPHENS.

Convention Notices.

☞ The Mahoning Valley bee-keepers will hold their 13th meeting in the Town Hall, at Berlin Centre, Ohio, on May 5. All bee-keepers, and the public in general, are invited to attend. Do not forget to bring your wives, children, and a well-filled lunch basket. We expect a grand meeting.

L. CARSON, *Pres.*

H. A. SIMON, *Sec. pro tem.*

☞ The semi-annual meeting of the Western Bee-Keepers' Association will be held at Independence, Jackson County, Mo., on Saturday, April 28, 1883, at 10 a. m. Papers prepared for the occasion by the president, secretary and others will be read, and matters of general interest to bee-keepers discussed. A general attendance of persons interested in bee-culture is requested. The present membership of this Association control 2,000 colonies of bees.

S. W. SALISBURY, *Sec.*

Kansas City, Mo.

J. A. NELSON, *Pres.* Wyandotte, Kas.

☞ Quite a number of the leading bee-keepers of Missouri and Kansas met at the Court House, in Independence, Mo., December 23, 1882, and organized a bee-keepers' convention, which was named the "Western Bee-Keepers' Association," by electing the following officers for the ensuing year: Jas. A. Nelson, of Wyandotte, Kans., President; L. W. Baldwin, of Independence, Mo., Vice-President; S. W. Salisbury, Kansas City, Mo., Treasurer. The Association passed a resolution to invite all bee-keepers within a convenient distance, to meet with us at our next meeting and lend us their councils. Adjourned, to meet again at Independence, on the last Saturday in April next, at 10 o'clock, a. m. J. D. Meador, P. Baldwin, C. M. Crandall, *Committee.*

☞ The spring meeting of the Western Michigan Bee-Keepers' Association will be held at Supervisor's Hall, Grand Rapids, April 26, at 10 a. m.

F. S. COVEY, *Sec.*

Coopersville, Mich.

☞ The Union Bee-Keepers' Association will meet in Grange Hall, Eminence, Ky., on Thursday, April 26, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, *Sec.*

Christiansburg, Ky.

☞ There will be a meeting of the bee-keepers of Western New York and Western Pennsylvania, to adopt a constitution and by-laws, elect officers, etc., for the Western New York Bee-Keepers' Association, on April 28, 1883, at Fredonia, N. Y., opening at 10 o'clock a. m. All bee-keepers are cordially invited to attend. Discussions on bee-culture, etc. Suitable rooms will be provided.

U. E. DODGE, *Acting Sec.*

☞ The Tuscarawas Valley Bee-Keepers' Association will hold their next meeting in the Town Hall, Coshocton, O., on Wednesday, May 2, at 10 a. m. All bee-keepers are requested to be present.

J. A. BUCKLEW, *Sec.*, Clarks, O.

☞ The spring meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, May 8, 1883.

M. C. BEAN, *Sec.*

☞ The Iowa Central Bee-Keepers' Association will hold their semi-annual meeting at Winterset, Iowa, on Friday, May 11, 1883. All interested in anything pertaining to bee-culture are invited to attend, and bring anything that will be of interest to the bee fraternity.

A. J. ADKISON, *Pres.*

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., April 23, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESSWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—There is no excitement in the honey market, but sales are fair to our regular trade. Offerings are plentiful of extracted and comb honey. Extracted brings 7½c. on arrival. The sales of comb honey are very slow, although there is a large supply of first-class quality on the market. It brings 12½c. on arrival.

BEESSWAX—Comes in slowly and brings 20¢/30c per lb., according to quality. CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15¢/16c. for white, and dark unsalable. Extracted, very little trade is being done in. 7½c. is about the market.

BEESSWAX—3½¢/3½c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Buyers are readily obtained for choice comb or extracted at full figures, but off qualities meet with slow sale.

White comb, 14¢/17c.; dark to good, 11¢/13c.; extracted, choice to extra white, 8½¢/9½c.; dark and candied, 5¢/7½c.

BEESSWAX—We quote 30¢/33c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Very quiet; dull. Comb at 14¢/16c.—some inferior sold at 10c.; strained at 6½¢/7c., extracted at 7½¢/8½c., lots in small packages more.

BEESSWAX—Scarce and wanted at 35c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18½¢/19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17¢/18c. Extracted very dull at 9¢/11c.

BEESSWAX—None in market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22¢/23c.; 2 lb. sections, 20¢/22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESSWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

☞ Mr. James Heddon announces on another page that he cannot supply any more Hives, etc., in the flat. All interested should notice the advertisement.—*Adv.*

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

☞ Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

☞ Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

An Instantaneous Light.

Such in a word is the unique apparatus on exhibition at the rooms of the Portable Electric Light Co., 22 Water Street, Boston. It occupies the space of only 5 square inches, and weighs but 5 pounds, and can be carried with ease. The light, or more properly lighter, requires no extra power, wires or connections, and is so constructed that any part can be replaced at small cost. The chemicals are placed in a glass retort; a carbon and zinc apparatus, with a spiral platinum attachment, is then adjusted so as to form a battery, and the light is ready. The pressure on a little knob produces an electric current by which the spiral of platinum is heated to incandescence. The Portable Electric Light Company was recently incorporated, with a capital of \$100,000, under the laws of Massachusetts. The usefulness of the apparatus and the low price (five dollars) will no doubt result in its general adoption. Some of the prominent business men of the State are identified with this enterprise. In addition to its use as a lighter, the apparatus can also be used in connection with a burglar-alarm and galvanic battery.—"Boston Transcript," Dec. 30.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred.

Will the various manufacturers of the Standard Langstroth hive please send circulars giving accurate dimensions, as made by them, to S. X. Clark, Delavan, Wis. The result as to the different sizes will be published in the AMERICAN BEE JOURNAL.—*adv.*

New Catalogues and Price Lists.

We have received the following new Catalogues and Price Lists of Bees, Queens or Apiarian Supplies:

G. B. Jones, Brantford, Ont.
 Elvin Armstrong, Jerseyville, Ill.
 Geo. W. Baker, Lewisville, Ind.
 Dr. Wm. R. Howard, Kingston, Tex.
 W. G. Russell, Millbrook, Ont.
 J. H. Tilley & Bro., Castle Hill, Me.
 Thos. J. Ward, St. Mary's, Ind.
 C. R. Mitchell, Hawkinsville, Ga.
 G. H. Knickerbocker, Pine Plains, N. Y.
 A. C. Kendel, Cleveland, O.—field, garden and flower seeds.

In Mr. S. Corneil's excellent article on "Ventilation of Bees," in last week's JOURNAL, on page 200, an omission was made, when putting it in type. In the second column, 28th line from the top, after the period, add the following sentence: "It is just so with the air."

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

On the next page may be found the advertisement for a "comb foundation fastener," by D. C. Talbot, of Elroy, Wis., to which attention is invited.—*adv.*

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Golden Italians Again!

One Golden Italian Queen, warranted purely mated, \$1.50. One purely mated and tested, \$2.50. One pure Queen, not warranted, \$1.00. All the above Queens are of the finest stock in the country. I sold over 300 last season, and had but one complaint. Full colonies ready to ship, for \$10.00, safe arrival guaranteed. 17Att
 L. J. DIEHL, BUTLER, IND.

E. T. LEWIS & CO., Toledo, Ohio,

 Still they go—Bees for business all ready to ship. Send for our new Circular of Queens, full colonies and nuclei; it tells how to introduce queens.

T. S. HALL,
 16A2t Kirby's Creek, Jackson co, Ala.

Bee-Keepers' Handy Book,

Or, 22 Years' Experience in Queen Rearing.

Opinions of Eminent Apiarists of its value:

From Geo. W. House, Fayetteville, N. Y.—"The information gained by a careful study of the new method of Queen Rearing, I consider worth \$100 to me. It supplies a long felt want to every Queen breeder and dealer, and is invaluable to any bee-keeper."

From James T. Norton, Winsted, Conn.—"I have read your book with much satisfaction and profit; it is written concisely and to the point. It should be in the hands of every bee-keeper."

From Rev. D. D. Marsh, Georgetown, Mass.—"Your book on Queen Rearing has been received. I am very much pleased with it. It is refreshing to see how frankly you have divulged the hard-earned secrets of your long experience. Your book contains a great deal of that information, which those who have already taken the 'first lessons' in apiculture will find new and valuable."

It will be remembered that Mr. E. T. Flanagan, of Belleville, Ill., went to Kenner, La., in March last to rear early Queens. After receiving the book he wrote me thus:—"I would have cheerfully given \$500.00 to have had your book and apparatus here when I first came. I am rearing 300 Queens."

From L. C. Root, Mohawk, N. Y., and one of the most prominent apiarists in America—"Your book has been received. Its title, 'TWENTY-TWO YEARS' EXPERIENCE IN QUEEN REARING,' is enough to convince any bee-keeper that they cannot afford to be without it. Good Queens is the rock upon which bee-keeping rests. I predict a large sale for the work."

From J. M. Hicks, editor of the bee department, American Grange Bulletin. Mr. Hicks is well known to nearly all bee-keepers in the west—"Book received. I pronounce it the best work of the kind, of American publications. I consider it a perfect gem for the practical bee-keeper, and should be in the hands of every apiarist."

Until May 1st the book will be sold for \$1.00 per copy. After that date, \$1.25 per copy, handsomely bound in cloth, and \$1.00 bound in paper. Fractionable parts of a dollar can be sent in postage stamps.

Our new circular and price list of Queens for 1883 contains 32 pages, and is illustrated to show our new way of rearing Queens. Send your address on a postal card for it.

HENRY ALLEY, Wenham, Mass.

FOR EXCHANGE.

Comb Foundation Machine for pure Italian Bees. Address, S. LONGLEY, CINCINNATI, O.
 17 In perfect order. 17A 1t.

The Bee-Keepers' Guide,

OR, MANUAL OF THE APIARY.

9,000 SOLD IN SIX YEARS.

100 Thousand Just Out.

More than 50 pages, and more than 50 fine illustrations added. The whole work has been thoroughly revised, and contains the very latest in respect to bee-keeping. It is certainly the fullest and most scientific work treating of bees in the World.

I had hoped and expected to make the price one dollar, and it has been so advertised by Mr. James Haddon and in Alley's new book; but owing to the increased size and expense, this is impossible.

PRICE, BY MAIL, \$1.25.

Liberal discount to dealers and to clubs.

Bees and Honey in Ancient Times.

In the books of antiquity, honey is mentioned as one of the most ancient articles of food—man's first source of nourishment. Aye, and are we not informed that when "the morning stars sang together" over the pristine beauty of a new born world, that under the bright smile of Heaven, Adam and his happy spouse were presented with a glorious home in an enchanting garden filled with "supernal fruits and flowers" of Heaven's own planting—nurtured and watched by hosts of angelic attendants, who had made that Eden-home a beautiful Paradise? There "the beasts of the field and fowls of the air" dwelled together in perfect harmony, under sun-lit skies; and among the beautiful bowers of that holy retreat, Eden's feathered songsters rapturously joined in "the swelling chorus."

There, too, reveling in the precious nectar yielded from the bloom of glory-clad hills, shrubs and flowers, was "the little busy bee," with its joyous hum and rapid flight—gathering the plenteous sweetness for the tiny but numerous family about to spring into existence, at its little home! Ever did it flit from leaf to leaf and flower to flower, gathering the honeyed treasures, that its "stores" may be abundant for generations yet unborn—when winter's sable-shades might settle down upon the earth, visiting it with cold and storm, chilling the "little pets" by its frozen breath or fiercer blast!

No historian has transmitted to our day a description of the rude hive provided for the bees that Noah carried into the ark, nor are we informed

whether Abraham's bees were kept in log-gums or box-hives, but it is recorded that the land where Abraham dwelled—Canaan—was one "flowing with milk and honey;" and when the old Patriarch, because of the famine that prevailed there, sent his sons to Egypt to buy corn, he sent as a present to the Egyptian ruler some of Canaan's famous honey. We may well conclude that Canaan's honey was then as famous as in subsequent ages was the honey from Mount Hy-mettus in Greece.

In later years, Abraham's offspring journeyed through the deserts of Arabia, and in order to sustain them there, God gave them manna from Heaven, to eat; they said that "the taste of it was like wafers made with honey." When the Amorites came out of the mountains of Sier against the children of Israel, "they chased them like angry bees." In the Mosaic law we find many statutes regulating the ownership of bees. When Jonathan was engaged in battle with the Philistines and became tired and faint, he partook of honey, and was greatly refreshed. David and his army was provisioned in Gilead, and honey was one of the luxuries enumerated. The Jews placed honey before their guests as a sign of welcome, giving them the greatest luxuries that the land produced. Jeroboam sent his queen with presents to the Prophet Ahijah, and included honey. In the tythes of the Jewish Priesthood, honey is enumerated. Job signified the plenteousness of honey in the land, by speaking of "brooks of honey." Solomon, relished Canaan's delicious honey, and volunteered this advice: "My son eat thou honey; because it is good." Isaiah mentions "the bee that is in the land of Assyria," and declares that bees were so plenty that "butter and honey shall every one eat that is left in the land."

The earliest mention of honey as an article of commerce, is, that the Jews

were engaged in trading it at Tyre, that old and honored mart of trade in Phœnicia. Sirach, who lived about the time of the re-building of the Temple of Jerusalem, speaking of the necessities of life, mentions honey, with flour and milk. Solon, in the year 600, B. C., enacted a law, requiring that bee hives in cultivated fields, must be 300 feet apart. Homer, Herodotus, Aristotle, Cato, Varro, Virgil, Pliny, Columella, and other ancient sages, composed poems, extolling the activity, skill and economy of bees. The celebrated Cilician apiarist Aristomachus, of Solus, with 58 years of experience in bee-keeping, wrote on the subject of bees and honey, some 500 years, B. C.—but that work is lost to us. The Persians, Grecians and Romans, used honey quite extensively as an article of diet; they also used it largely in *preparing* their food, and by it, most of their beverages were sweetened.

More than 3,000 years ago, it is said that Samson proposed this riddle to the Philistines: "Out of the eater came forth meat; and out of the strong came forth sweetness," and gave them seven days to expound it. They are said to have been unable to explain it, and by threats of burning his wife and all her kindred, they extorted the explanation from her, as follows: "What is sweeter than honey? And what is stronger than a lion?"

Samson was not only a riddle-maker, but was himself a riddle! It is said that while he was quietly walking, unarmed, in the vineyards at Tim-nath, "a young lion roared against him," and "he rent him, as he would have rent a kid." "After a while, he turned aside to see the carcass of the lion, and, behold, there was a swarm of bees and honey in the carcass of the lion." Thereupon we are told that he commenced to regale himself on the honey, and gave of it to "his father and mother, and they did eat." This was the key to his riddle.

Of course it was very singular that he should have slain a lion in the prime of his vigor, and yet more strange that a swarm of bees should have taken possession of the carcass.

This remarkable story of ancient times is full of enigmas. In explanation of some of these, Oedman remarks as follows:

"The lion which he slew had been dead some little time before the bees took up their abode in the carcass, for it is expressly stated that 'after a time' he returned and saw the bees and the honey in the lion's carcass; so that if any one here represents to himself a corrupt and putrid carcass, the occurrence ceases to have any true similitude, for it is well known that in those countries, at certain seasons of the year, the heat will, in the course of 24 hours, so completely dry up the moisture of the dead animals, that without undergoing decomposition, their bodies will long remain like mummies, unaltered, and entirely free from offensive odor."

In that country, it is said, that with wild beasts, birds and insects, coupled with the dry heat, a dead body is soon cleansed from all corruption, and the bones are clean and white, and a swarm of bees may readily have used such a carcass for a hive. We do not propose to attempt to clear the story of all difficulties, but will draw some lessons from Samson's very singular adventure.

In those days, among the Hebrews, Romans, and Greeks, honey appears to have been about the only sweet, and was used in place of sugar, then unknown. Honey was then considered among the necessities of life. It is true that Pliny, Galen, and some other authors allude to *succanon* as a white crystallized gum obtained from an Indian reed, which was sometimes used as a medicine, and was "brought from Rome, in pieces about the size of a nut." The Arabians were first to bring sugar to notice, after they had pushed their victorious arms into the Western regions.

The first writers by whom sugar, as such, is mentioned, says an author, lived in the 12th century, in the time of the crusades. Albert of Aix states that the soldiery, when near Tripoli, in Syria, pulled up the sweet stalks of a reed grown there abundantly in the fields, and called *zucra*. Its wholesome juice refreshed them, and was so grateful to their taste that they were incessantly sucking it. This valuable plant was diligently cultivated every year. When ripe for harvest, the natives crushed the reeds in a mortar, pressed out the juice,

and preserved it in vessels till it became thick and granulated, and resembled snow or salt in its whiteness.

In the year 1306, when *Samudo* compiled his *Mysteries of the Crusaders*, the sugar cane was not yet cultivated in Sicily, though it was then already grown extensively in the Morea, in Cyprus, and Rhodes. A century later it had become so common in the island of Sicily, that the infant Don Henry, of Portugal, readily obtained there a supply of plants for its introduction in Madeira. From here and from the Canaries it was carried to America, where it has been so extensively cultivated that the European plantations were speedily abandoned, and America now supplies with sugar not only nearly all Europe, but a large portion of Asia also. The sugar cane was first brought to the Western Hemisphere by the Spaniards.

Another writer remarks as follows on the consumption of honey:

The consumption of honey and wax, and consequently the demand for them, was so great among the Romans, that the production thereof was an object of the highest importance in rural economy; and no one was deemed qualified to manage a farm who did not thoroughly understand bee-culture as then practised. This was to be made an essential source of revenue to the proprietor, for the Romans were a practical people, who, according to Columella, looked to an increase of annual income in their pursuits more than to a mere gratification of taste. But the natural supply of honey in Italy was insufficient for the home demand, and large quantities were imported from Africa, Crete and Sicily, the superior quality of which induced the Italian bee-keepers to send the finest and most aromatic of their own to market under the name of Sicilian and Cretan honey, as we are informed by Varro. That of inferior quality, as we learn from Pliny, they were in the habit of coloring and sweetening by an admixture of other substances, and strengthening by the addition of various kinds of wine. An annual tribute of honey and wax was imposed on conquered provinces and territory, as on Pontus and Corsica, and the hope of obtaining additional supplies, it is supposed, was among the inducements for their invasions of Germany.

A large amount of honey was required by the religious ceremonies and worship of the people. "Nothing is sweeter than honey," says Varro, "grateful to Gods and men. It is used on the altars." It was particularly prominent among the sacrifices of the peasantry. The numerous rural deities, whose favor and protection they invoked, and to whose service they were attached, claimed a portion not only of the products of their gardens, orchards and fields, but of their flocks and herds, and of their apiaries. Also at the feasts of the Gods, described by Ovid, which required costly aliments and precious wines, the delicious honey-cake was

never wanting. These were composed of meal, honey and oil, and had to be equal in number to the years attained by the offerer. For the domestic worship also of their household deities—the *Penates*—honey "the gift of the Gods," was indispensable; and it constituted a large item at the vernal consecration—*ambarvalia*—of their fields in April, as well as at the annual thanksgiving in October, and likewise at the special worship of Ceres in November, who was regarded as the "flock increaser," and the "honey dispenser," and who, by her union with the rain-god Zeus, caused fruitful seasons. Her priestesses were called "bees," because honey was the first food of the infant Dionysus, the son of Bacchus, whom Ceres bore in her arms, as Isis carried Horus; and she was the instructor of Aristæus in bee-culture. Bacchus, too, demanded a share, as the "discoverer of honey," the "admirer of all sweetness," and the "decorator of the blooming meadows."

Every sacrificial victim offered to the higher Gods was sprinkled with milk, wine and honey, and large quantities of the latter were required in the solemn celebration of their mysteries, and in the obsequies of the dead. The later Romans poured honey in the grave of the deceased. It was with them a symbol of death. It will hence readily be inferred that their religious ceremonies involved a large consumption of honey, and that this must have induced increased attention to bee-culture. But the quantity used in domestic economy was still greater, as they were unacquainted with the sugar now in common use. What they called *saccharum* was a very different article, obtained from Arabia and India. It was, as we learn from Pliny, used only medicinally. Honey was thus the only sweetening employed by them for meat and drink, and was as indispensable in their households as sugar is now in our families.

In view of the death-dealing adulteration of sweets in our day, is it not our duty to imitate Samson, who, when he had found the God-given pure sweet—honey—sought out his relatives and took some of it to them to eat?

Thousands and tens of thousands of children are dying all around us, who, because their ever-developing nature demands sweetness, crave and eagerly demolish the adulterated "candies" and "syrups" of modern times. If these could be fed on honey, instead, they would develop and grow up into healthy men and women.

Children would rather eat bread and honey than bread and butter; one pound of honey will reach as far as two pounds of butter, and has, besides, the advantage that it is far more healthy and pleasant-tasted, and always remains good, while butter soon becomes rancid, and often produces

cramp in the stomach, eructations, sourness, vomiting and diarrhea. Pure honey should always be freely used in every family. Honey eaten upon wheat bread is very beneficial to health.

The use of honey instead of sugar for almost every kind of cooking, is as pleasant for the palate as it is healthy for the stomach. In preparing blackberry, raspberry or strawberry short-cake, it is infinitely superior.

It is a common expression that honey is a luxury, having nothing to do with the life-giving principle. This is an error—honey is food in one of its most concentrated forms. True, it does not add so much to the growth of muscle as does beef-steak, but it does impart other properties, no less necessary to health and vigorous physical and intellectual action! It gives warmth to the system, arouses nervous energy, and gives vigor to all the vital functions. To the laborer, it gives strength—to the business man, mental force. Its effects are not like ordinary stimulants, such as spirits, etc., but it produces a healthy action, the results of which are pleasing and permanent—a sweet disposition and a bright intellect.

How astonishingly appropriate is even its name—honey! Derived from the Hebrew word *ghoney*, literally it means DELIGHT. Humanity may, therefore, delight itself with honey, as long as the sun endureth!

To Our Exchanges.—We have prepared the first article in this paper with especial reference to its adaptability for general reading, and respectfully invite the editors of our Exchanges and others to copy it into their papers. It contains information of value to the general public, and should be read by every one interested in providing a pure sweet for the young, middle-aged and old,—both food and medicine. Bee-keepers who desire to increase honey consumption, should send to us for an extra copy, and personally take it to the editors of the local papers of the county, and ask them to copy it. We print a large edition this week, and will supply it free for this purpose, while any are left.

By the Review, Butler, Ind., we learn that Mr. L. J. Diehl has lost only 4 colonies out of 160, during the past winter. Generally the losses have been very light, and the prospect for a good honey crop is excellent.

The Partridge Pea.—Prof. A. J. Cook, in the *Rural New Yorker*, gives the following concerning this honey plant:

Among the many plants which I receive each year from the bee-keepers throughout the United States, as furnishing abundant nectar for the bees, no one comes more frequently, or from a wider range of territory, than the partridge pea—*cassia chamaecrista*. Like the clovers, this is a leguminous plant, and like its near relative, the cow pea, it not only furnishes nectar from the flowers, but even more abundantly from extrafloral glands situated on the peduncles. Gray speaks of this as more abundant southwards; but I have received it very frequently from Iowa, Northern Illinois and Wisconsin. The flower is bright yellow, and the habit of the whole plant is quite attractive. The Pulse family is very rich in bee-plants, as will be seen by the following list: White and alsike clover, mellilot, or sweet clover, locust, wistaria, Judas tree, honey locust, and the cow and partridge peas. We thus see that the Pulse family, like the Mint and Composite families, are of great importance to the apiarist.

Queen Rearing.—Mrs. L. Harrison, in the *Prairie Farmer*, gives her views on her *modus operandi* of queen-rearing, thus:

We like all kinds of bees, yet Italians have our preference; they are proof against moths, cling to the combs better, and are more enterprising than the common bees of the country. Italians are so common that we doubt if there are many pure German bees now in this country.

Persons who have kept bees for any length of time have noticed that some colonies, whose conditions are the same as the remainder of the apiary, produce more honey than others. These colonies are the ones to breed from, if honey is the object in view. If a colony is deprived of its queen, in six hours the bees will be constructing cells to raise another. Worker eggs, or larvae not over three days old, are used for rearing queens. Some breeders claim that the best results follow when the bees have access to eggs only. Bees seem to prefer to raise queens on new white combs; such an one should be given to the breeding colony, and placed in the centre of the hive; holes might be cut in it, making convenient edges for the bees to attach their queen-cells, so that they can be easily removed, if desirable to do so. On the third day this comb should be given to queenless bees, and they will immediately commence enlarging cells. On the twelfth day, if it is desirable to preserve the queens, all cells should be removed but one, as the first one that emerges will destroy all rivals. Those who make a specialty of rearing queens, remove the frame to an incubator and examine it, often removing the queens to a nucleus, as fast as hatched. Those who have not a con-

venience of this kind, can cut out the cells, and give them to nuclei, previously formed long enough to have cells of their own. We have had many cells destroyed by giving them to newly formed nuclei, but never lose them if they have cells of their own. To save the time of inserting cells, we often wait until the bees have eaten off the outside covering, showing that the queen will soon be out, and then remove the cell with adhering comb, so that it will fit between the frames of honey, placing point downwards, and in a short time the queen is out. We preserve cells with variations; sometimes we place them over cages, similar to a cover of a tin pepper-box, only the tops are of wire cloth; and again cut out cells and put them into cages (made of wire cloth by rolling around the broom handle, with stoppers in each end), and place them in the cluster. If young queens are introduced, when they are only a few years old, they are generally well received.

System in the Apiary.—Mr. A. E. Foster, in the *Practical Farmer*, gives this very timely advice on systematic work in the apiary:

"A place for everything, and everything in its place." I know of no place (unless it is in the family) where this rule should be followed more closely than in the apiary. The prosperous bee-keeper is always in a hurry, needing different supplies as he examines different hives, and it is very necessary that he should know just where to find things as he needs them. If you have not this faculty well developed, cultivate it, by assigning everything in your apiary a place, and keep everything in its place. The time lost in hunting here, there and everywhere, for what you need, will amount to a great deal, more than any one would suppose; and it will not only save time, but keep you from getting in a bad humor, which generally follows one of those long searches. The mother who teaches her child to put things where it gets them, does the child good, and saves herself much trouble, in picking things up after it.

Mr. O. O. Poppleton has returned from Florida, where he has spent the winter, accompanied by his wife. They have had an excellent time, and look well. They brought us a sample of mangrove honey from the apiary of Mr. W. S. Hart, of New Smyrna, Florida. In the article, on page 213, entitled Bee-Keeping in Florida, Mr. P. points out two errors, which we correct with pleasure. They were, doubtless, inadvertently made by Mr. Lake in copying. The "bee belt" is 25 miles (not 125); and the red mangrove grows below the head of Indian river—not "above," as it is there stated.

CORRESPONDENCE

For the American Bee Journal.

The Best Bees—How Obtained.

JAMES HEDDON.

The following was received April 18, and I asked Mr. Hutchinson if I might insert it, at the head of my reply as an excuse for again coming forward with what, to me, is not the most pleasant of subjects to discuss at the present time.

MR. HEDDON.—When you have the time, please give us one more article on "The best bees—how they were obtained." Please tell us if the bees that you now have are any better than those you had when you first made the cross between the dark Italian and brown German, if so, in what respect, and what methods and selections were employed to bring about the desired results. What I wish to know is, if I would obtain as good results at once, by crossing the two above mentioned varieties, as I would to obtain some of your bees; that is, can I gain five years by commencing where you are now? Some bee-keepers have remarked, in my presence, that "Heddon's bees were nothing but hybrids; anybody can get hybrids easily enough, without obtaining his hybrid queens." Now, what I wish to know is, if your hybrids are superior to the hybrids that would naturally result, at once, from a cross between the dark Italian and the brown German varieties, or whether, by selection and care, you have developed a superior strain of hybrids; that is, superior to what would result naturally at once from a cross between the above mentioned varieties. In a year or two more, if I get well started in the production of comb honey, I shall cut loose from this band-business. I shall make the production of comb honey my speciality, then if any wish to obtain my queens they can take such queens as I know to be best, or they can let them alone. Now, it is my honest opinion that the kind of bees that you have, are the best for the production of comb honey, and I wish to know which is the simplest, easiest, quickest and best way to stock my apiary with such bees, and I feel certain that you will let neither modesty nor self-interest influence you in giving me advice upon the subject.

W. Z. HUTCHINSON.
Rogersville, Mich., April 16, 1883.

I started into this business with the purchase of 48 colonies of black or German bees, all in box hives except eight, which were in old-fashioned Langstroth hives. They were purchased of farmers about this vicinity, not buying more than six of any one person; generally gotten in lots of 1, 2 and 3. Six colonies were bought of one Mr. Southerland. Let us call these the S. bees. Not knowing enough about the business at that

time to keep busy all the time with this apiary, and bees being a new and mysterious thing to me, I spent many hours sitting close to the hives and watching the little sharp and industrious individuals come and go, and guard the entrance. I was not long in discovering that different colonies possessed remarkably different characteristics and looks. Right away I became attached to the S. bees, and the superiorities that these colonies plainly manifested, were very well marked in each and every colony. With these superior traits, was a marked physical difference; these bees were all larger and lighter in color than any of the other 42 colonies. Five colonies purchased of Mr. H— were the meanest and most worthless colonies in the apiary. Every colony was vicious, and seemed to spend most of their time "seeking whom they might devour." They never looked into the surplus boxes that season. The season was the worst in my experience. But little honey was gathered, and the 6 S. colonies (all in box hives) had more than all the rest added together. The 5 H. colonies were the smallest and blackest bees in the yard. Ever since I have noticed that traits and marking like the above, keep company with each other wherever I have seen German bees.

A few seasons later I got bright three-banded Italians of several prominent breeders. These Italians possessed some points of merit over my brown S. strains, but on the whole, they were not their equal for the apicultural pursuit of dollars and cents. Crosses between the two races were a cross "cross." I wished I had never seen them. I wrote against the Italian bee, and the trade in them. The "hybrids" were pretty good workers, better than the pure Italians, but too irascible for comfort. While I was freely exclaiming my disgust for these Italians, Mr. Oatman, of Dundee, said to me: "If you will just try some of my stock, which is of the dark leather-colored Dadant importation, you will become a convert to the Italian bee. I feel sure."

Always open to conviction, I tried once more, and sure enough, I did find these bees vastly superior to the bright, shorter bodied Italians. At the time of their advent into my apiary, I had bred my colonies, nearly all, to these brown Germans, and, as I suppose all do, who breed bees, had selected colonies of the best qualities to breed from. This was forced upon me, as I was somewhat mixed up with some of the inferior blood. Not much so, however, as severe winter losses had assisted me to rapidly get rid of this blood. As good as these dark Italian bees were, the brown bees still possessed some marked traits of superiority over them. Of course, crossing between these races took place at once, and I soon had the happy privilege of observing bees that possessed more valuable characteristics, valuable to him who wants profit from the business than either one of the races in their purity.

A curious fact here presented itself. None of the crosses (or hybrids) be-

tween the brown German and dark Italian bees were bad in temper. Both of their parent strains were the mildest of their races, and the crosses are just as amiable as any bees I ever handled.

That was about six or seven years ago, and since that time I have, in as great a measure as practical, directed the breeding and crossings, and without knowing the reason why, colony No. 36 gathered more than No. 29, and believing that whatever the reason might be, the law of hereditary claimed it for its own. I have bred from the colonies that gave me the most surplus honey, and were the best behaved toward their operations and each other. These two, have I made the vital points. I soon learned that I need not care for the number of rings. Two years ago I sold to Mr. Shirley my Glenwood apiary. At that time the bees were of my mixed races, as mentioned above. Mr. Shirley is an energetic and skilled apiarist, and a master at breeding, but he has a fancy favoring the rings, and he has, in breeding, added to my list of good-nature and honey gathering qualities, the other point of three bands, and he works with my bees here some every season, and I cannot but believe that he will agree with me that he cannot see that his bees are any better, in any respect, than my hybrids, as Mr. H.'s acquaintances are wont to call them. They are hybrids, but I avoid the use of that word, for it has been made to sound ugly, because of the old irascible crosses that went by that name. I think that Mr. Hutchinson has made a wise determination, and one that he will not regret. I am satisfied that, with good bees, proper fixtures, and the clear calculation of Mr. H., the production of comb honey has far more profit with it than any queen business.

This is not all. I find that the time has come when large numbers of bee-keepers are looking at the matter as does Mr. H. and myself, and I predict that, within two years, four-fifths of the bees sold in this country, will be ordered for their merits, and not for any special number of bands.

I have frankly told you of my experience in the matter, and once more given my deductions, drawn from that experience, and I leave Mr. Hutchinson to answer the rest of his questions from the reasonings of his own brain.

Dowagiac, Mich.

For the American Bee Journal.

Old Foggy's Plan of Bee-Culture.

FRANK B. RIFE.

The terrors of winter has passed, which has kept our little workers confined for so long; spring has opened again, and the busy hum of their wings is heard from morning till night, gathering the nectar from the wild flowers.

I wintered my bees on the summer stands, with excellent results. I put 13 on a long bench in November, and boarded up the west side, so as to be

a protection against the west winds, and they came out all right this spring, all being very strong but two, which were weak in the fall. Bees, in this locality, are booming this spring; they are getting such an early start on the elms, etc.; the peach bloom is just coming in, and the prospect is good. I dealt considerably in the fur business this last winter, which afforded me a great deal of traveling; in which I paid the greatest attention to bees and the different methods of bee-keeping, during the winter. I saw all kinds of bee hives, from the old-fashioned log gum, to the finest movable frames, and among them all, the Langstroth hive is my choice, for it has more advantages than any other hive that I have seen. I inquired of all the bee-keepers I met, their method of management, and their opinion of the movable frame hives, and found that all who had used the movable frame hive, were well satisfied there with.

I fell into company, for a night, with an old man who keeps bees in the old log or stump hives. Quite a number of the old log gums were scattered throughout an old half-pruned orchard, which looked like so many stumps or ash gums, and, seeing no supers or caps, I asked the old gentleman how he obtained a surplus of honey from his hives, as I saw no caps. "Caps! What do I want with caps? I see, young man," said he, "that you know nothing at all about bee-keeping and honey taking, and I will tell you something about bees and honey, and my experience is worth listening to. In the first place, cut down a hollow lime or sycamore tree, saw off 25 or 30 hives; then cut and nail a clapboard top on each of them, then bore four auger holes about the middle of each; now, make two tapered pins and drive into them." "Why make the pins tapered," I asked. "I will tell you by-and-by. Chink around the tops with rags, and they are ready for the bees. After the bees have stood in them for four years, they are old enough to take. To take the honey, you must do this: About harvest, take a gum, turn it upside down, set an empty one on the top, draw a sheet around the joint where the two gums meet, drum on the lower gum with a stick, and scare the bees up into the empty one. Three or four can take hold of the gums and lay them upon a couple of good, stout fence rails, laid sloping upon the fence. Now bring a bread tray to catch the dripping honey, pry off the head of the hive, roll up your sleeves, and go to work with your smoker and knife, and you will soon have a tub full of honey. After you have emptied the old hive, place the new one, and the bees, on the old stand, and you will be all right. But they will not do to take until they are four years old. You see you can have 8 or 10 to take every harvest, and always have a supply of honey on hand." "Exactly," said I; "but do you not believe movable frame hives would be ahead of all your plans?" Tut, tut," said he, "I have never seen one, neither do I want to; I have heard enough about

them to know that my plan is much better; much better, sir. Don't you see that a hive full of drawers and shelves would discourage the bees, and wouldn't be worth a cuss. If you want to raise bees, you take my plan, and you will have lots of bees and lots of honey, and become well satisfied that I know all about bees."

Mr. Vaught and myself, of Washington County, Mississippi. The labor and shipping cases are not deducted from the proceeds. We consider the season of 1882 as more than an aver-

age one, but by no means extraordinary.

Judge Harriman's report is excellent, when you consider the great loss of swarms; his apiary is in a grove of forest trees, and he failed to clip his queen's wings, and, besides, he neglected his bees, owing to his judicial and plantation duties.

Bee-keeping is a science, and requires a great deal of study. With a reasonable amount of enthusiasm, hard work and strict attention, one man can attend to 100 colonies.

With comb foundation as a guide, that the bees may build their combs straight; with the movable frame, to manipulate your combs and bees with ease; the uncapped knife and extractor, to remove the honey by centrifugal force; the smoker to quiet the little workers, and the queen cage to control and introduce your queen—with this furniture, so to speak, you are prepared for work; and without any one of these you will certainly fail.

Honey should be taken from the hives almost as rapidly as the bees gather it, at least every ten days; and when they are bringing in the nectar rapidly, I extract from every comb that has any honey, even in the brood-chamber, and when not capped over; running the extractor slowly enough to discharge the honey without throwing out the eggs and larvae. In a few hours there is enough honey stored for feeding the young bees. When the honey flow slackens, go slow with your extractor, and never extract when the flow ceases. I ripen the honey by evaporation in large tanks covered with cheese-cloth.

I ship in new cypress barrels of 525 pounds net, and comb honey in 25 pound cases.

We never plant anything for bees in this rich alluvial country. Every tree, shrub and plant yields more or less honey. I have never known bees to be afflicted with any disease.

To make a specialty of bee-keeping on a large scale, there is nothing that pays more for the capital invested, but do not suppose there is no hard work in it. The bee-keeper only goes to church in swarming season, when the sun goes down.

These figures seem extraordinary, yet they can be exceeded by the gentlemen with their present experience and a good season.

Greenville, Miss.

For the American Bee Journal.

Importing Queens from the Orient.

FRANK BENTON.

It seems, when one is away off, out of the pale of civilization, folks do not always get the stories they hear about him straight, and, I am sorry to say, it looks as though some do not quite want everything to be known just as it is. The item about me on the first page of the BEE JOURNAL for Oct. 18, 1882, which, though true, and evidently published in good faith by the editor, was very liable to create an incorrect impression among bee-keepers. As therein stated, I was quite

sick during last summer; indeed, at three different times during the year, my life was jeopardized, and, of course, I did not rear as many queens as I had hoped to be able to. But I think the season's showing is fair, considering the peculiar difficulties under which one must labor in cultivating bees in the Orient; and the fact that the "Mt. Lebanon Apiary" had to be wholly created after I came to Beyrout, at the beginning of last year, which latter fact should be noticed, since parties in America stated in 1881, that the apiary had already been established at Mt. Lebanon. It was during my first illness in 1882, that Mr. T. B. Blow, of Welwyn, England, called on me in Beyrout, having previously visited me in Cyprus, where I left him when I came to Beyrout to start the apiary there. He, alone, is capable of understanding the numerous difficulties with which I had to cope at that time. As soon as possible earthen pots and cylinders containing bees, were purchased to start up the new apiary, and the work of transferring colonies, rearing and shipping queens began. It was at this time that the weather was unfavorable, cold rains, then later warm rains, with bright warm sunshine between the driving showers. In June I was very sick with cholera morbus again. In July came the sad loss of our only little one. Following this was a serious attack, resulting, the physician said, from too great exposure to the fierce tropical heat of the sun in Cyprus in preceding years.

We had been obliged to "flee to the mountain" on account of the condition of my health, and the Moslem outbreak in Beyrout (which, in the BEE JOURNAL of Aug 16, 1882, was wrongly located in Cyprus). The cool air of the upper Lebanon did me good, and as soon as it was safe I returned to my work. Notwithstanding these interruptions, I was able to send out, during the season of 1882, queens to the number of 340, and 3 full colonies (a small amount of honey and wax were also sold). Of these, 179 were addressed by express, directly to Mr. D. A. Jones, of Canada, while a number of the rest were sent by mail to parties in England, who, it was expected, would forward a portion of them to Mr. Jones. From the latter I never received any definite statement as to how many of these queens were safely received, but only the assertion that many failed to get through. The cause of poor success in shipping those sent by express, was greatly owing, I believe, to the method of shipping prescribed by the gentleman just mentioned. The only shipments to America made during the past three years, that have been eminently successful, were two lots (one of 30 queens in 1881, and one of 42 queens in 1882), put up in accordance with the plan I proposed upon first landing in Cyprus in 1880. I have met with fair success, sending queens from Cyprus and Syria by mail to different parts of Europe, except when, this last year, some 40 fine Syrian and Palestine queens were seized in London, and sent to Paris (having been

mailed at a French post-office in Syria), after which I got them back at the end of about six weeks, all dead!

I sent the first queens by mail from Cyprus to Europe in June, 1880, as can be seen by reference to the *British Bee Journal* for July, 1880, where the method employed is described and the cage illustrated. With this form of cage as a basis, changing from time to time conditions of putting up to, suit the season of year, and as further experience suggested, I think I have, with the help of one modification suggested by a friend in England succeeded in finding out how to be successful in sending queens from the East to distant lands. It must be borne in mind that it is a journey of 3,000 miles, 1,500 of it by sea, in a sub-tropical climate, where hot desert winds are particularly trying for the bees, which are buried in the ship's hold, under tons of other mail matter.

During the coming season I shall try to send some queens by mail from Europe to America. I believe I would have succeeded in doing this, last year, had not the 40 queens been seized in England; for some of these packets were experimental ones addressed to Mr. D. A. Jones. Some of the English postal regulations are very troublesome, and, among these, is that which excludes queen-bees from the mails. The bee-keepers of England ought to protest *en masse*, and keep protesting until permission is granted to send queens by mail. This is surely one reason that has tended to make the introduction of Italian and other improved bees very slow in England. Our British cousins, so progressive in many other respects, have not even a packet post, without which we would hardly think we could get along.

Athens, Greece, March 30, 1883.

Written for the Kansas State Board of Agriculture

Bee-Keeping—Past and Present.

HIRAM J. WARD.

The subject of bee-keeping has claimed the attention of many of our most learned men of ancient and of modern times, who look upon it as a science worthy of their study and their philosophy, finding in the honey bee an insect worthy of better care and attention than it formerly received. Gratwell, Schirach, and Huber the elder, were among those of antiquity who devoted their time and wisdom to the advancement of the knowledge of the habits and character of these insects; and to the latter, especially, we are indebted for much that is of estimable value in the studies of the naturalist. Although he became blind at the early age of 15, his works gave an impulse to this branch of rural industry in Europe, which caused the management of bees in common hives to be brought to a high degree of perfection; his experiments being conducted by his affectionate wife, and going so far as to count a full colony one at a time. Debaucy, in the forefront of this cen-

tury, invented his movable-frame hive, but it was found to be inconvenient for general use, and it has been improved and improved, until we now have hives to suit all men.

At the present day the bee-keeping world are agitating the production of the *Apis-Americana*, or the "coming bee," that it is hoped will be able to reach the nectar in our deepest flowers—such as red clover, thistles, etc., and will produce one, two or three hundred pounds of honey per colony. The idea of stripes or color has passed away with specialists, and now they breed for business. Occasionally one, who still sticks to the common black bee, warmly defending their excellences. While we all have to agree that they produce the whitest of comb honey, I think I can safely say that nine-tenths of the bee-keepers of to-day would prefer the Italians, for they possess more excellences than any other strain that has been introduced yet; being more docile than the blacks, also much larger, and can carry heavier loads against our strong winds, and breed faster—keeping their hives full of workers. My advice to all bee-keepers would be to Italianize all of the bees in their neighborhood, and then they can be sure of keeping their bees pure. But if they allow any black colonies to be kept within two or three miles of them, they will have to be very watchful if they get any purely-mated queens, because the queen goes out in the air to mate, and the black drones being smaller and swifter, outstrip the heavy Italian; and the consequence is, you have a queen producing hybrid bees. This can be prevented by any judicious apiarist, to a large extent, by rearing drones from the best Italian colonies, cutting all drone comb out of the black colonies, and not allowing them to rear any drones.

The hybrid bees has admirers, too, for they produce beautiful comb honey, and are very industrious; very often storing more than either the blacks or pure Italians; but they are more irascible than the pure of blacks or Italians, often being very annoying to everybody and everything that moves. But anyone can put up with considerable trouble to be rewarded with a lot of choice honey, for they are indefatigable workers. They, too, are larger than the blacks, although they do not all have stripes. Some of them are pure black, while others have stripes across their abdomen; and, in fact, are pure Italians. Yet queens reared from these will have hybrid drones—the drones being what the mother is; if she is pure Italian, her drones will be pure Italian; if she is black, the drones will be blacks; or hybrid, the drones will be hybrids.

While many of our best apiarists advocate breeding from the swarms that store the most honey, irrespective of the color of the queen or drones, others recommend selecting a pure colony to rear queens from, and select their best working colony to rear drones from. I have never reared queens only for my own use, and I have always selected good, large bees,

and as near pure as possible, to breed queens from; taking my second best for drones, and preventing any others from rearing drones by removing all drone combs, or cutting the drones' heads off, just before they are ready to hatch; and I have a strain of bees now that winter well, and store as large an average as any in this country. My average for 1882, was 82 pounds per colony, the yard through, although my best went 120 to 140 per hive. One-third of my surplus was in small sections, weighing from 1 to 1½ and 2 pounds each. Honey put up in such packages sells readily, when compared with the surplus boxes that were formerly used.

A word to those who are thinking of investing in bees will be in order now; and it will be the old adage used so often: "Make haste slowly." By this I mean, do not invest in more than two or three colonies at first, for they will multiply faster than you will learn to handle them; and if not properly cared for, your profits will come out on the debtor side. Beginners must have a little adaptation to their work, or they will fail to reach the financial goal; for bee-keeping now, and in the future, is not as it was when "father kept bees." It has been reduced to a science, and will be more scientific in time to come; only those that keep pace with the improvement, and have a liking for the business, will be successful—and bee-keeping is becoming a specialty with hundreds of scientific bee-keepers. It should be a separate occupation, for the simple reason that any one posted in the improvements up to the present, can produce honey cheaper than those who have only a colony or two out back of the smoke-house, which are looked after only in swarming-time, or time to rob, by killing them. Let the same person just raise one more hog, and when fattened and sold, it will buy more honey from any practical apiarist than he would get from his two or three colonies, with less trouble or money invested. Indifferent or careless bee-keepers allow the bee-moth to accumulate, and by so doing, make it more labor for the successful bee-keeper to rear good business bees, upon which he depends for the bread and butter for his family and himself.

Again, where a man has a love for the business of handling bees, it is a very remunerative employment, and will give him valuable lessons of his duty toward his fellow-man; also teaching him that great results often have small beginnings. For instance; each head of clover contains about 60 distinct flower tubes, each of which must, therefore, have a portion of sugar not exceeding the one-hundredth part of a grain. The proboscis of the bee must consequently be inserted into 500 clover tubes before one grain of sugar can be obtained. There are 7,000 grains in a pound, so that for every pound of sugar procured in this way, 3,500,000 flower tubes must be emptied. Honey, however, contains three-fourths of its weight of dry sugar, so that every pound of honey is equivalent to more

than 2,500,000 clover tubes sucked by bees. Yet how few people realize, or even have one thought of the amount of labor performed by the industrious honey-bee, in storing a hundred pounds of surplus honey. Nor do they think how rapidly they increase, for it is known that the queen has deposited as many as three to four thousand eggs in 24 hours; and in 21 days they all emerge from their cells perfect bees, there being about 35,000 to 40,000 workers in a good colony. It would only take a few days to rear a full colony if they did not work themselves to death; but the entire colony becomes new, every two to three months during the working season, owing to the amount of honey obtained and distance traveled in gathering it. Some people may think this a wild assertion, yet after 14 years' experience, I know what I speak; and to any one that does not believe it, I would say, try it yourself, as I have. By getting an Italian queen, and introducing her into a black colony, in three months they will not find a single black bee in the hive if the queen is a pure Italian; and it is a conceded fact that the Italians are the best, all things considered, for general use, although we have in the United States six different strains of bees—the common black, Italian, Holy Land, Syrians, Albinos and German—all having their friends, although the Holy Land and Syrians are very cross, while the Albinos are the most quiet in handling, and also slower in honey gathering, often not storing enough for their own use; while it is claimed that one cross of either two of these kinds improves them, with the possible exception of Italians, that are susceptible of weeding out a little in order to secure good honey gatherers.

I think for the specialist the Langstroth hives are the best, because they are capable of tiering up, by putting one above the other in time of a large honey flow, and when the apiarist is taxed to his utmost to give the bees room to prevent swarming, and thereby secure the best results in surplus honey. They are also well adapted to the storing of comb and extracted honey; and being in general use, all of the supply dealers have hives, frames and sections, in the flat, ready to put together, singly or in any amount wanted; and specialists are adopting the same hive, in order that they can order, on short notice, surplus sections, and have them fit without trouble. I have used the original American hive, patented by H. A. King & Co., of New York city; the hive being 15¼ square by 21 inches high, outside measurement, with nine movable frames in them; the top part of the frame being 1½ inches wide, forming a complete floor or the top to the hive, when all of the frames are in, and each frame has a slot ¾ by 2 inches through them, for the bees to pass through into the surplus boxes above, and it is my opinion, that for farmers or those who want only a few colonies, that the American is the best hive they could use; but would advise any one who intends to invest in bees, to visit a

well-established apiary and look at the different hives in use, and there he could learn more in one day, in a practical way, than he would learn from books in a month. Our most practicable apiarists advocate the necessity of students spending one season in the employ of a specialist, thereby learning the trade, so to speak, at the end of which time they are competent to take charge of an apiary of 80 to 100 colonies, with reasonable certainty of making a success of it; and I can speak for all bee-keepers, and say that, as a class, they are always willing to give advice to beginners, or if visited, will show them the advantages of the different hives that they may have in use. It will repay any one for such a visit, to see the different kinds of bees, for almost all bee-keepers have two or more strains, and they are all looking for the coming bee, the *Apis-Americana*.

Farmington, Kansas.

For the American Bee Journal.

Queen Rearing, Raspberry Honey, etc

P. P. N. E. PELISSIER.

I was surprised, on reading an article by W. C. Jennison, on page 119. He must use hard lumber to make his frames. Let him use soft pine and he will find that by pulling a little on the fine wire, or passing a piece of iron or hard wood over it, it will be imbedded sufficiently deep, so as not to interfere with the scraping of wax or propolis.

As for queen-cells, if he lets his bees swarm naturally, he does not need to cut queen-cells over wires, and thereby spoil his well-built worker-combs; he has simply to destroy those that he does not wish to hatch. If he wants to rear queens, the best way is to have frames without wires, fasten one or two bars (according to depth of frame) inside of the frame, parallel with the top and bottom bars; fasten a strip of foundation to each of these bars, and set one or two of these frames in the centre of the hive containing the best queen. In less than 24 hours, the comb foundation will be drawn out and every cell will contain an egg. Every bee-keeper knows how to have the queen-cells started, and he will have no difficulty in cutting them out large enough so that they can be simply fastened on another frame with a common pin, which will save the mutilating of combs.

The statement that Mr. Jennison clipped from the *American Cultivator* is wrong, so far as red raspberries are concerned. The flowers of red raspberries yield whiter, nicer and better-flavored honey, and in larger quantities than even the much-praised white clover.

The bees are good judges of honey; they will invariably gather from the bloom that yields the richest nectar, even if the secretion is not so great as in other bloom. Here, the white clover is of spontaneous growth; it may be seen everywhere; if a fire

runs into the forest, fire-weed and white clover will generally grow the same summer; fire-weed makes excellent fall pasturage for bees. It yields honey from Aug. 15 to Oct. 1.

I have hundreds of acres of white clover and red raspberries within reach of my bees, who invariably desert the white clover the moment raspberry bushes begin to bloom.

Bees are in splendid condition, wintering finely; mine were put in the cellar on Nov. 10, and look as if they could bear confinement three or four months longer; this, I attribute, to the thick, wholesome honey they have in the hives; honey gathered from raspberry and goldenrod. We are having the coldest and dryest winter in the memory of the inhabitants.

Every one seems to have set his mind upon a standard frame. Why not adopt a frame 10 inches deep by 15 inches long, inside? Such a frame will contain 150 square inches, which is about the average size of frames in use. The Langstroth is too shallow to winter successfully in the North, and almost all other frames are too deep for the production of comb honey with success; besides, if we run for extracted honey, by using a second story, we have a hive of just the right height; whereas, if deeper frames are used, I would not like to use a second story, in a locality exposed to high winds.

Pelissier, Quebec, March 10, 1883.

For the American Bee Journal.

Section Racks, Crates and Separators.

W. H. B.

The leading questions, just now, are, What sized sections, and What kind of a rack or crate shall we use, to hold the sections in place on the hive, for comb honey? After experimenting considerably with different kinds of crates, I have settled on this as the rack. It is very simple; if made properly will adjust itself to the top of the hive, although it may not be level; it is just the thing for tiering up, whether used with separators or not. It suits me, and all that I have shown it to, and who have used it, think it about right.

For sections, 5 or 6 inches deep, slit out the stuff $1\frac{1}{2}$ or 2 inches wide (turn up edgewise, to nail together); for small sections not more than one inch wide. (I prefer to use sections running parallel with the frames, for several reasons). I cut two pieces $\frac{1}{4}$ inch longer than the length of the sections, in a row, from front to back of hive; these are the side pieces for the rack. Next cut the end pieces $\frac{1}{2}$ inch longer than the width of the section, from side to side of the hive, adding to them the thickness of the side pieces. Nail them on the ends of side pieces with one nail in each corner. This will let it adjust itself to the top of the hive. Cut some sticks, as long as the width of the hive, one inch wide, and as thick as the space between the top bar and the top of the hive; place these sticks crosswise of the hive, so that they will

come under the ends of the sections, when they are placed on; (these sticks will kill less bees than putting on a whole crate, filled with sections, at once, and I think it is more easily cleaned). Lay on the frame and fill it with sections and separators, if you use them, key up with a stick, which is as long as the length of the rows of sections, 1 inch wide and $\frac{1}{2}$ inch thick, having one edge chamfered off. For tiering up, place a block on each side of the top of the lower section rack, just long enough to hold the upper rack at the proper height. The bees will work in sections without separators sooner than with them (especially if the sections are small), but I find objections. One year, I fastened the sections together (without separators) before placing them on the hive; took them off and sold them, just as they came from the hive, and being fastened together, I could not assort them. I had something over 7,000 lbs. in this condition, and I lost 3 cents per pound on the lot, by not having it properly assorted, and my customers would have been better pleased. If, in a crate, there is some dark honey on the outside, it is a hard matter to make a customer believe it is white clover in the middle. I find, when separators are not used, with large sections, and honey is not coming in rapidly, the bees are sure to fill one side at a time of the combs, near the outside of the section crate; this causes the combs to curl into the next section; this makes trouble, and often the outside section will not be filled on the outside. With separators we have none of this trouble. Small sections will be filled nicer without separators than larger ones, and sometimes so that they can be glassed.

Oran, N. Y., March 7, 1883.

For the American Bee Journal.

The Best Hive for all Purposes.

DR. J. S. MCALLISTER.

My experience differs considerably (from what would seem to be that of Mr. Heddon's) in regard the Langstroth frame, and my experience in bee-keeping dates back nearly 40 years, when we kept from 30 to 100 colonies in the old-fashioned way. I have traveled some, and am acquainted with many very successful bee-keepers who, together with myself, do not consider it safe to keep a valuable colony of bees in the Langstroth hive (the year round). As far as surplus honey is concerned, either comb or extracted, I believe that there can be as much secured with side storing as top storing, with the proper sized frame and hive to hold them, and I think of all the sizes in use, the "American" comes the nearest to the most practical size.

With a plain hive, about 2 ft. long, a bee-keeper can have 8 frames for a brood nest, and room at each side for 18 one-pound sections, making 38 at a time, by placing them in edgewise to the brood frames, and leaving room on the top for as many more as he may wish. I like but very little upward

ventilation. The past winter I wintered 24 out of 25, the brood nest being sealed and packed nearly as tight as a drum, except that the entrance was open about 2 inches; the colony that died was ventilated the most. I use tight top-bars and winter on the summer stands. On page 601, of September number for 1882, headed an Amateur's Success, is a partial report for what I done with 3 colonies. The full increase was 27, and with the honey to take out of the hives this spring, will make the surplus honey the product of the 3 colonies and increase, nearly 500 pounds. I, like many others, have the pure unadulterated Italians, and I am starting an apiary at a point where there are no other bees kept for more than 20 miles, in any direction, for the purpose of keeping them pure.

Columbus, Neb., April 20, 1883.

Practical Farmer.

Making Ready for the Harvest.

W. G. PHELPS, M. D.

Nothing goes so far towards assuring success in bee-keeping as a state of preparation for the forth coming honey season. This preparation consists not simply in having surplus hives ready for expected swarms. To be prepared in every sense of the word, means, 1, well-populated hives; 2, accessible surplus department; 3, the use in boxes of starters or comb foundation; 4, right management at the right time.

Taking up these essentials, in the order named, let me explain. A well populated hive means a hive well crowded with bees at the opening of white clover bloom. This can be accomplished best by the stimulative method, and by feeding up. You may ask, "does it pay?" Yes, tenfold; particularly if your bees are short of natural stores, and are gathering none from without. Not that the bees convert the sugar fed them into honey, but rather into bee muscle, which, taking wing untiringly, gather nature's sweets, to store it, in more than compound ratio, for the owner. A normal colony of bees contains not less than 20,000 of these industrious insects. The younger portion of these assume the duties of nurses and wax-workers, while the other workers become the veteran honey gatherers. A less number of bees than above stated will store up for their owners much less honey, in proportion, than if up to or in excess of that. What I mean is thus illustrated: Two colonies, each consisting of 12,000 bees, would, as ordinarily kept, store no honey in the caps. The same bees combined in one colony, would yield, even by the simplest management, from 50 to 100 pounds. The reason is this, about so many bees are necessary to keep up the required heat of the hive and do the "chores," or household work, so as to speak. They will not enter the surplus boxes, unless conditions as regard heat, wax-working, etc., are all right. They are less able to defend their house against

robber bees, and many stay home for this purpose who would otherwise become honey gatherers.

2. Accessible surplus department.—Let our bees be ever so strong, if the depository for the surplus comb honey be not accessible, the bees will be loth to enter it. To work and transform the wax (a secretion of their bodies) into the wondrously-formed honey comb, requires a heat of at least 85 degrees.

3. Use of "starters" or comb foundation.—"Starters" are simply pieces of nice natural comb fastened with melted wax to the top of the box. In the absence of combs, comb foundation may be fastened to the top, in the same manner. The use of it can be relied upon to increase the yield of honey from at least 25 to 50 per cent. It encourages bees to commence work in the boxes, and saves them a vast amount of work in comb building.

4. Right management at the right time.—Many who keep bees make a great mistake in putting on boxes long before it is expedient to do so. Wait until the clover bloom is just ready to open, and then beware of putting on too many at once. Meanwhile keep all openings in the honey board well closed and the cap filled with dry leaves, chaff or cut straw, to prevent loss of heat from the breeding department.

Galena, Md.

For the American Bee Journal.

Putting Foundation in Sections.

M. C. SMITH.

The accompanying engraving shows a machine for putting in full sheets of foundation in section boxes, which I made in March, 1881. I used it last

season to put in over 3,000 full sheets, with entire success. The table which holds the pot, is made of tin, cut 7 inches square; the edge is turned over and pressed down to give strength. The legs are cut out of tin, 1½ inches wide; the edges turned over and pressed down, and long enough to raise the table ¾ inch above the lamp, to prevent smoking. Any lamp will do to melt the wax. The pots are gill cns, with oil can spouts attached, as shown in the cut. A common oil can, with handle, will do as well as the pots. The block, to the left, is to hold the foundation in the centre of the section, while being fastened, and

is made of 1½ inch board, 8 inches long, by 6 inches wide. No. 2, cut to fit inside of the section, and of the right thickness to hold the foundation in the centre. Fasten No. 2 in the centre of No. 1. Cut the foundation to fit without warping; place it in the section on No. 2; hold the block in the left hand, in such a manner as to allow the drop of wax to run down along the section and the edge of the foundation. From 1 to 3 drops will fasten it on both sides and top. Leave the foundation ¼ of an inch from the bottom of the section. Go to your tin-smith with the above description; he will make the tin work, lamp and all, for less than 75 cents; you can make the wood work yourselves.

This is the way I put foundation in brood frames by a Press. When the wax is ready, dip the board in the wax once; now you have two thin sheets. Lay one on the dies; on this put the wired frame; now lay on the other sheet, close the die book, and press the two sheets in one. By this plan you press the wire into the centre of the foundation. By this method the wire will not cut the foundation.

Last season I prepared between 300 and 400 frames, as described, and the bees built every one out into as beautiful combs as I ever saw. You can hive a bushel of bees on these frames with success, every time.

Starkville, N. Y.

For the American Bee Journal.

Saunders Co., Nebraska, Convention.

The Saunders County, Nebraska, Bee-Keepers' Association, met April 28, 1883. The fact that a large amount of honey was being imported into this State was stated as an argument for a greater effort toward home production. To this was coupled the statement that 200 colonies to the square mile could not gather all the honey.

A report of members on wintering showed 252 colonies put into winter quarters. Out of that number 48 colonies perished. Many apiaries were not represented.

There has been a heavy loss of bees during the winter in this county—some largely engaged in the pursuit losing from half to two-thirds of their colonies.

C. C. TURNEY, Pres.

J. J. BURTON, Sec.

Convention for Northern Iowa.

There seems to be a number of bee-keepers in the northern counties of Iowa. Why could not a meeting be held at some central point on the C. M. & St. P. R'y.? How many vote aye?

J. G. BENNETT.

Emmetsburg, Iowa, April 27, 1883.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

When to Pack Bees for Winter.

Will Mr. James Heddon please answer the following queries in the BEE JOURNAL: What is the best time for packing or preparing bees for winter? What is your opinion in regard to packing them in the forepart of December, in such a winter as last winter has been? I would like the opinions of as many leading bee-keepers as possible on those queries.

Bristolville, O.

J. S. BARR.

ANSWER.—I have never yet been able to prove satisfactorily to myself, that very early packing was a benefit. By all means, I should aim to pack my bees at such a date that they would have a good chance to fly several times, and the first, immediately after the packing, and get thoroughly acquainted with their new quarters. I have maintained for years that I do not get any advantage from late breeding, and I do not want any undue early breeding either.

Wired Frames.

Please answer the following questions in the BEE JOURNAL:

1. In wired frames what size of top bar do you use, and which is the best way to punch holes in them?

2. How many wires for a Langstroth frame, and how near to the end bars should the first wire be?

3. How near should foundation fill the frames?

4. Is it not a difficult job, even with Given's wiring frame or machine, to get the wire just right, so that the end bars just so go in?

5. Should the wire be stretched tight, or must some allowance be made for it to give, when the die book is closed, so that it will not break?

H. W. FUNK.

Bloomington, Ill.

ANSWERS.—1. I use a top bar 3¼x¾, and bore them on a boring machine that bores all the holes, in about ten bars per minute.

2. I use only eight wires per frame, and I use them all vertically. The end ones should not be further than ½ inch from the end bar.

3. I maintain, against Mr. Root and others, that it is better and safer against all bulging, that there be a space of ¼ inch between the foundation and each end bar, and ¼ to ⅜ at the bottom. Heat expands the wax sheets.

4. I use the Given press for all wiring, and with the lye process, I always make up all my frames com-

plete, and wire them before I put in the foundation. I now have no trouble. Two of my students are, this moment, in an adjoining room filling wired frames (a steady jog) at about three or four to the minute, and the perfection of the work, makes it fun for all who witness it. I wish every reader could see this work.

5. No; the wire should be woven quite loosely, as the action of the dies will take up the slack when the pressure is brought to bear upon it. These answers are applied to wiring with No. 36 wire for machine pressing, and not No. 30 and hand pressing.

Transferring Bees.

1. Regarding your new method of transferring bees, where do you place the old and new hives, after the first drive?

2. If I unite the second drive with the first, will they cast a swarm before the honey season begins?

Devizes, Ont. JOHN S. RIDDELL.

ANSWER.—1. After the first drive we place the new hive directly on the old stand, and the old hive a few rods away to a new stand, unless we mean to put the second drive into the same new hive, thus avoiding any increase, when we place the old hive only a few feet away, and then off to one side, and partially behind the new hive.

2. No; you will not do this driving till the honey season is just opening.

Freaks of a Queen and Bees.

I am still desirous of "more light." The queen that I spoke of as "coming to," on April 2, is "performing" curiously.

1. On my first examination, after she was introduced to the little colony in the nucleus hive, I found that she had commenced to deposit her eggs "all in order," i.e. only one in a cell. Upon a further examination, to-day, I found that she was distributing them quite freely through the few combs, that are in the hive, but instead of one egg, there are from one to five. How can this be explained?

2. Here is another wonderment to a beginner like me. In looking over my colonies, to-day, I found one that had been queenless, but they have provided themselves with a young queen, that probably is not more than 48 hours old, and in the whole hive there is not a singly egg or larva to be found. What can be done with this young queen? There are no drones in my apiary, how am I going to save this colony and queen?

H. B. HAMMON.

Bristolville, O., April 25, 1883.

ANSWERS.—1. This can be accounted for in the following ways: 1. Drone layers (unfertilized queens) are apt to lay a plurality of eggs in a cell.

2. Some otherwise good fertile queens sometimes have this fault. 3. A very prolific queen will often do so when cramped to a small comb surface. I presume this is the trouble in your case.

2. You have a plain case of superseding of a "played out queen." The bees reared this young queen from the eggs of the old one, which old one departed about the time the bees began the new queen. When the new one hatched, of course there was no brood young enough to be in the egg or larval state. You are about in my latitude, and should have drones flying in a few days. As queens often become fertilized 10 to 15 days (and sometimes, we are told, 20 days) after birth, there is hope for this queen, and my way would be to let the matter alone ten days or two weeks, and then examine the combs for eggs.

SELECTIONS FROM OUR LETTER BOX

A Cold Wave.

We have had a cold now for nearly a week; the mercury standing at 18° above zero, two mornings. Yesterday we had 2 inches of snow with a searching wind. As elm and soft maples were in bloom a week ago, I set the bees out of the cellar, only to get them caught by this cold wave.

G. M. DOOLITTLE.

Borodino, N. Y., April 26, 1883.

Queen Rearing—Killing Tree Worms.

The time is near at hand, with us, when apple trees will be in blossom, and that is about the time when many of us begin to sort our nuclei, for queen rearing, that we may have queens ready, so that our strong colonies may be divided and be in readiness for the honey harvest. Other hives may have queens that are old, or for some other cause need superseding. I have been in the bee business for 27 years, and have spent much time and money in rearing queen bees. All who have but a few colonies of bees, and especially for those who have more and wish to improve them, should procure the new book of Mr. Alley, which gives the results of 22 years experience in queen rearing. This tells all about how to get good, hardy, prolific queens whose progeny will be hardy, healthy and good honey gatherers. It talks good sound sense, and is what every bee-keeper should have before him. When I sat down to write, I thought I would tell something about what a hard time we used to have, killing the worms on our apple trees, but, as I have run away from that subject, I will only show how we destroy them now, as it is so much nicer than the old way. If we

do not kill the worms, they will kill the trees. We arm ourselves in the following manner; first, we want a pole long enough to reach the highest nest; on the top end tie a rag about as large as a dish-cloth, or smaller; next we want some lye in an iron kettle, or something convenient to carry it in; the lye need not be very strong, only strong enough to crack the skins of the worms; dip the rag end of the pole into the lye, and give them one sop, when they are in the nest. If you have never done this, you will be surprised to see the amount of worms you will kill in a few hours. I prepare the lye in the following way: Fill a kettle one-half full of wood ashes, and fill it up with water; set it on the stove and bring it to a boil; this will be strong enough.

W. H. BALCH.

Oran, N. Y., April 23, 1883.

Bees Strong and Ready for Harvest.

My bees are all right. I had 114 colonies in the cellar; and have lost six; some weak colonies I have doubled up, reducing them to 100 good and strong. I am now ready for the honey harvest.

J. STEWART.

Rock City, Ill., April 28, 1883.

Prospect for Honey Never Better.

The prospects for a good honey harvest in this locality was never better. There is an abundance of white clover, catnip, etc., which will be in bloom by the middle of this month. My bees are all in good condition, and are very busy on the fruit bloom, which is now at its best. I had two fine swarms,—one yesterday and one to-day—the earliest I have ever had. I am now busy forming nuclei and dividing up, so as to be ready to take in the rich harvest when it comes.

ELVIN S. ARMSTRONG.

Jerseyville, Ill., May 2, 1883.

Burned Up.

My house, with all its contents, has been destroyed by fire. My bees got a scorching, and one hive was burned up. They had wintered well. I lost one for want of food, and one was burned up, leaving me 13 colonies now.

WM. MOWBRAY.

Sarnia, Ont., April 28, 1883.

Preventing Stings, etc.

Mr. J. H. Stephens, Riverton, Iowa, wishes to know an antidote besides whisky, to prevent the dreaded "business end" of his bees, when walking in the yard. He says that the bees have a natural dislike to him, which can be avoided by taking a small dose of whisky, peppermint or anything that will change the smell of his breath, which the bees seem to dislike, and which exasperates them to stinging. Wash the hands and face with the same ingredient, sweetened with a little sugar; this will impregnate the skin with odoriferous perspiration, which the bees seem to admire, instead of the objectionable perfume the body has during manipulation. In the spring of 1882 I bought one 3-frame nucleus to begin with. I

increased them to 6, in good condition for winter. On the first warm day in April all were doing well, with the exception of two which were weak in numbers. One was robbed, through my own carelessness, so that I have five to begin the season with. I extracted, in the first week of September, 80 lbs. of goldenrod honey. I would like to ask G. B. Jones, Brantford, Ont., if the three entrances spoken of, on page 210, are more serviceable to winter, than one on a tight bottom-board? JOS. M. WISMER.
Jordan Sta., Ont., April 28, 1883.

Bee-Keeping in Ireland.

You can scarcely imagine with what interest I have re-read the able articles, during the past year, in the AMERICAN BEE JOURNAL. Do not let me miss any number of this volume. Long may it be cater for us all. We have had a very long, wet cold winter, and it has tried our plans of wintering. I hope we may all have a good honey season. WM. DITTY.
Newtownards, Ireland, April 19, 1883.

Bees Breeding Up.

My bees came through in first-class order. They are breeding up to very strong colonies at the present date. All that were put up, either in cellar or in chaff receptacles on the summer stands, with chaff box cushion cover, lived and are in good trim. Those left upon the summer stands unprotected, and with tight honey-board, took Heddon's "pollen disease," and about 10 per cent. died.

E. L. BRIGGS.
Wilton Junction, Iowa, April 30.

Still Cold in Northern Ohio.

There is a cold north wind to-day, with a clear sky; the ground was frozen this morning. The past week has been cold, with two or three mornings that the thermometer ranged from 27° to 30°. Bees have flown but little, and the maples, elms and willows that were furnishing them such fine forage have, of course, been blighted.

P. F. TWITCHELL.
Andover, O., April 29, 1883.

Problem of Wintering Bees Solved.

The past winter has been the coldest ever known here; notwithstanding which, bees have wintered uncommonly well. I put 32 colonies in the cellar on the first of November, and took them out April 3. All came out in good order, after the five months confinement. They did not have a flight for 15 days, before being put into the cellar, last fall. The cellar, that my bees wintered in, during the past winter, was very cold; potatoes froze solid; and for weeks at a time the mercury stood at 12° below freezing, and I expected to lose heavily; but all came out right. I have been so uniformly successful with my method of wintering bees for the past 13 years, that I think that, to my satisfaction, the problem is solved. I have never lost but one colony, in the cellar, that did not starve to death, and that one was queenless, and con-

tained only a few old bees, when it was put in. The result of my experience, in wintering bees, entirely fails to corroborate many of the scientific theories advanced by writers on that subject, and I am content to follow the course that has uniformly proved successful with me, regardless of what science may prove, if not sustained by experience. In a future article I will briefly give my method of preparing for wintering bees.

O. E. COOLEY.
Ridgeway, Iowa, April 26, 1883.

Un-poetic Bee-Culture.

We are having but little of the poetry of bee-keeping in this state. A poor honey season, followed by a winter, quite as disastrous to the bees here as was the winter of 1880-81. Many bee-keepers have lost all. My own loss is about 20 per cent.

W. J. DAVIS.
Youngsville, Pa., May 1, 1882.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., May 7, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey is very good, and arrivals are slow. We pay 7c/10c. on arrival. We sold, since last October, more than 600 barrels, and our stock is exhausted, while our customers are relying on us for supplies. Hope our friends will supply us. No demand for comb honey, and prices nominal.

BEESWAX—Arrivals of beeswax are good, and prices range from 3c/35c. for a good article.
CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15c/16c. for white, and dark unsalable. Extracted, very little trade is being done in it. 7c/9c. is about the market.

BEESWAX—A. B. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Buyers are readily obtained for choice comb or extracted at full figures, but of qualities meet with slow sale.

White comb, 14c/17c.; dark to good, 11c/13c.; extracted, choice to extra white, 8c/9c/9c.; dark and candied, 5c/7c.

BEESWAX—We quote 30c/33c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull; light jobbing sales only. Comb at 10c/14c.—Strained and extracted at 7c/75c. Couple lots of poor Comb sold at 10c.

BEESWAX—Sold lightly at 35c/36c.
W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Is a little lower, and at the lower price it has moved off a little better of late. 1-lb. sections of best white sold at 18c/19c.; second grades, 1-lb., 17c.; 2-lb. sections a little slow at 17c/18c. Extracted very dull at 9c/11c.

BEESWAX—None in market.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22c/25c.; 2 lb. sections, 20c/22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.
CROCKER & BLAKE, 57 Clitham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Our Premiums for Clubs.

Any one sending us a club of **two** subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For **three** subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For **four** subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For **five** subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Our stock of back numbers of this volume are now getting very low. Please look over your numbers, and if any are lacking, send us a postal card, giving the date of those you want, and we will send them, if not all gone. We give this notice, because, last year, several left it until the end of the year, and then requested us to send the missing numbers. Then it was too late, the numbers being all gone. Look them over now, and you may get them completed.

Foul Brood Pamphlet.—Wishing to be relieved of sending out my pamphlet on Foul Brood, I have made arrangements with Mr. T. G. Newman to supply them to the bee-keeping fraternity desiring them.

A. R. KOHNKE.
Youngstown, O., April 25, 1883.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Mr. Alley's new book on Queen Rearing will hereafter cost \$1.25

We have received his Circular and Price List for 1883, which contains 32 pages, and make a nice appearance.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Convention Notices.

The Iowa Central Bee-Keepers' Association will hold their semi-annual meeting at Winterset, Iowa, on Friday, May 11, 1883. All interested in anything pertaining to bee-culture are invited to attend, and bring anything that will be of interest to the bee fraternity.

J. E. PRYOR, Sec.

A. J. ADKISON, Pres.

The Southwestern Iowa Bee-Keepers' Association will hold its annual meeting at the apiary of L. E. Mercer, Lenox, Taylor county, Iowa, May 26, 1883. Meeting called at 10 o'clock sharp. Forenoon: Election of officers. Afternoon: Work in the apiary, when any question, with regard to handling bees, will be practically explained. Accommodations will be provided for visitors from a distance.

W. J. OLIVER, Sec.

There will be a meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association on Tuesday, May 15, 1883, at Mr. E. Whitlesey's, two miles south of Pecatonica, Winnebago County, Ill.

J. STEWART, Sec.

Rock City, Stephenson County, Ill.

We have a few copies of our pamphlet entitled "Bee Culture" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.

Borodino, N. Y., Aug. 15, 1883.

18A4t 5Bit

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

WANTED, by one who has had quite a considerable experience in bee-culture, to engage with a practical apiarist for the present season. No correspondence solicited but by those who are masters of the business. Compensation required according to services rendered. My age is 64—health good. Can go anywhere on short notice. Address, L. N. TONGUE, Box 43, Elroy, Wis.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Poisoning Troublesome Bees.

We have recorded many cases where persons, who object to bees being kept near their premises, have resorted to poison to rid themselves of a supposed or real annoyance.

For several years we had from 50 to 100 or more colonies of bees on the lot behind the BEE JOURNAL office, and in the fall, when there was nothing for the bees to gather, they became very troublesome to neighboring grocery stores. In one case they invaded the store and drove out not only the customers but the clerks and the proprietor also. The latter came to us with his sad complaint and protest, and only regained possession of his store by the use of brimstone. It was hard on the bees, but they were trespassers, and we entered no protest. In order to avert further trouble with our neighbors, as well as the city authorities, the bees have been taken into the country.

Now, suppose, that these bees had been poisoned, what an amount of trouble it would have entailed!

We have reports from California and other localities where trouble has been experienced in the same direction—and, in some cases, poisoning were resorted to.

Our attention has been called to this matter afresh by the following article, kindly sent us by some unknown friend, in a copy of the *Young Scientist*, published in New York. The editor remarks as follows:

CAUTION TO BEE-POISONERS.

From notices in several of our exchanges we learn that some thoughtless and ignorant persons, urged by

so-called scientific men who certainly ought to know better, are attempting to destroy by poison such bees as annoy them. Aside from the fact that such a practice is contrary to law, to good morals, and to right feeling, those who think of adopting this vile practice should remember that it is not at all impossible that they may take the life of something much more important than a few bees. Some human being may fall a victim, and then the poisoner may find himself in the clutches not only of a guilty conscience, but of the law. Nor is it necessary that man, woman or child should find access to the vessels set out for the destruction of the bees; unless under extraordinary conditions the bees will carry to their hives, before they die, an amount of poisoned food sufficient to render the honey in their combs virulently poisonous.

This is not a mere surmise or theory, but a fact, which, some years ago, we demonstrated clearly and fully to our own satisfaction. The records of the experiments were unfortunately destroyed in the great fire which consumed the "World Building" last January, but the results were so clear and unequivocal that we can give them from memory without any material inaccuracy.

In these experiments we established small colonies of bees in locations where they could not interfere with other colonies, and selecting times at which food was scarce, we fed them upon syrup to which poison had been added. In every case we succeeded in destroying the bees, but it was only in a very few cases that we failed to get poison from the honey in the hive, and in these cases the bees took the poison only when no other source of food supply was open to them. In many cases the bees that carried the poison to the hive did not seem to suffer till long after the young bees were all dead; in some cases the queen was amongst the very first to fall a victim, and next came the young bees, just emerged from the cells.

We used about a dozen different varieties of poison in our experiments, and we fed it to the bees at distances from their hives varying from three feet to a mile and a half. The latter, of course, was easily done by means well known to every bee-hunter.

When arsenic or Paris green was used we found no difficulty in detecting arsenic, by means of the usual chemical tests, in the honey taken from the hive. A little of the honey

added to the liquid in a Marsh's apparatus readily gave the beautiful characteristic arsenical mirror, and some of the honey fed to mice killed them very quickly.

Nor is this to be wondered at. The honey-sac of the bee is not a true stomach, but rather a muscular bag, which exerts very little action on its contents. This is readily seen in the case of the delicate odors of flowers which are retained by the honey in the comb after it has passed through the honey-sac of the bee. Hence, we have clover honey, basswood honey, buckwheat honey, etc.—all readily recognizable after they have been deposited in the hive. As might be supposed, therefore, when the bee has but a short distance to go, it invariably succeeds in depositing several loads of the poisoned honey in the hive before it succumbs. When the distance is very great the case is different, and many bees will then die on the way, or just after reaching their hives. But in ordinary cases it is only those bees whose hives are quite near that prove an annoyance, and they are the ones that are least affected.

To attempt to poison bees, therefore, is to attempt to mix poison with a common and much-valued article of human food, and the consequences may be of the most serious nature. We feel assured that all that is necessary, in order to put a stop to the practice, is the diffusion of accurate knowledge on the subject.

Bees in Southern Florida.—The Florida *Despatch* of last week contains the following item:

Mr. J. H. Hendrick, the apiarist of Cedar Key, has commenced transferring his Italian bees to a more Southern locality. Some time since he carried a colony to his new home at Indian Rocks, Clearwater Harbor, where he will move his large apiary as soon as the honey season is over.

After getting a Binder in which to place the numbers of the BEE JOURNAL, as received, Mr. F. L. Dresser remarks as follows: "The Binder for the Weekly BEE JOURNAL is received, and I am very much pleased with it. It doubles the value of the JOURNAL, which is saying a good deal."

Bee-Keepers' Guide.

Prof. Cook has just issued the Tenth Thousand of his Manual of the Apiary. The Professor issued the first edition himself (a 30c. pamphlet). Then the six succeeding editions were published at this office, and 9,000 copies have been sold in six years, which gives substantial evidence of its deserved popularity. The preface to the present edition reads as follows:

In 1876, in response to a desire frequently expressed by my apiarian friends, principally my students, I published an edition of 3,000 copies of the little unpretending "Manual of the Apiary." This was little more than the course of lectures which I gave annually at the college. In less than two years this was exhausted, and the second edition, enlarged, revised, and much more fully illustrated, was issued. So great was the sale that in less than a year this was followed by the third and fourth editions, and, in less than two years, the fifth edition (seventh thousand) was issued.

In each of the two following years, another edition was demanded. In each of these editions the book has been enlarged, changes made and illustrations added, that the work might keep pace with our rapidly-advancing art.

So great has been the demand for this work, not only at home and in Europe, but even in more distant lands, and so great has been the progress of apiculture—so changed the views and methods of our best bee-keepers, that the author feels warranted in thoroughly revising and entirely recasting this eighth edition (tenth thousand.). Not only is the work re-written, but much new matter, and many new and costly illustrations are added.

In this edition, the author also assumes the duties of publisher. In bidding adieu to the old publisher, I wish publicly to express my high appreciation, and deep sense of obligation for the able manner in which Mr. Newman has performed his share of the work. I shall still hope for his wise counsel and advice, from which I shall surely profit in the future as in the past. For this, as also for the able opinions of many other of the first apiarists of America and Europe, I wish to express most grateful acknowledgments.

It is the desire and determination of the author that this work shall continue to be the exponent of the most improved apiculture; and no pains will be spared, that each succeeding edition may embody the latest improvements and discoveries wrought out by the practical man and the scientist, as gleaned from the excellent home and foreign apiarian and scientific periodicals.

It is, perhaps, needless to say that this Manual covers the entire ground of apicultural research, and that it is practical and progressive throughout.

Prof. Cook is an entomologist, a botanist, a passionate lover of the honey bee, and his Manual is an admirable work for all—valuable alike to the beginner and the more advanced apiarist.

"Artificial Honey."

Mr. E. C. Jordan, of White Sulphur Spring, Va., has sent us the following from Mrs. Dr. Looekerman, of Alexandria, Va., describing the methods of making "artificial honey," as given in the Receipt Books of that State:

It is a well-known fact to those even of a small degree of experience in the matter, that honey, taken from the hive in warm weather, soon deteriorates; that it loses its finest qualities, by the separation of its sugar and the fluid composing it, the result of vinous fermentation. The honey collected by bees is sometimes found to be actually poisonous (see numerous authors), while the honey we present to the readers of the *Old Dominion* is so complete a concentration of pure saccharine as to be entirely removed from all liability of becoming acidulous. It is not known to be subject to any other change by age than that of becoming granulous or candied. And, hence, in the estimation of those who have been favored with this receipt, it deserves the title of Superlative Honey. Put one pint of water and a quarter or third of an ounce of alum into any nicely cleaned kettle, over a bright fire, and bring to a brisk boil. Set the kettle off, and into the solution therein put four pounds of number-one crushed or granulated sugar. Stir together, place over the fire and bring it to a sharp, brisk boiling for one or two minutes; remove from the fire and strain through a light cotton cloth. In cold weather use a little more water. When cool and flavored, let it stand two days before using.

FLAVORING FOR SUPERLATIVE HONEY.—Into a pint bottle put one ounce of Jamaica ginger, pulverized, some 12 or 15 drops otto of rose, and one pint best alcohol or New England rum; shake well once or twice a day for two or three days. A medium sized teaspoonful of the clear extract to five pounds of the honey gives it a most exquisite flavor.

And after all it is but an imitation of the pure article, though it costs as much or more than the genuine.

☞ The Fremont, Mich., *Indicator* says that Mr. Geo. Hilton laid a couple of boxes of nice honey on its editorial desk last fall, and adds: "It is remarkably fine, and a dish of it will make a man forget almost all his troubles." That is the way to do it. New honey will soon be here, and a nice box taken to the editor of the local paper will tell others where to get it.

The Time of Honey Bloom.

Mr. Alfred Mottaz, Ottawa, Ill., sends the following request:

"Will you please give in the *BEE JOURNAL*, the usual time of the blossoming of the principal honey plants?"

The best we can do in this line, is to give the following from Prof. Cook's new Manual:

ANNUALS OR PERENNIALS.

April—Skunk cabbage.
April and May—Dandelion, strawberry, ball, and black or blue sage of California.

May—White sage, of California, and seven-top turnip.

May and June—Horehound, of California, sumac, of California, coffee berry, of California, horse mint, of the South, false indigo, and lupine.

May to August—Ground ivy or sill.

May to Fall—Cow pea, of the South.

June—Stonecrop, of the South, mammoth red clover, California figwort, of California, and hemp.

June and July—White clover, alsike clover, sweet clover, horehound, ox-eyed daisy (a bad weed), bush honeysuckle, and partridge pea.

June to August—Matrimony vine, sage, and motherwort.

June to Frost—Borage, cotton, silk or milk weeds, mustard, rape, St. John's wort, and mignonette.

July—Corn and teasel.

July and August—Basilis or Mountain mint, catnip, asparagras, Rocky Mountain bee plant, Viper's rugloss (blue thistle), blue vervain or verbena, white vervain or verbena, and marsh milk weed.

July to Frost—Boneset, bergamot, figwort, giant hyssop, malva, iron weed, Culver's root, and Indian plantains.

August—Buckwheat, snap-dragon, touch-me-not or swamp balsam, great willow herb fire weed.

August and September—Golden honey plant, and large smart weed.

August to Frost—Spider flower, golden rod, asters, marsh sunflower, tick-seed, beggar-ticks, Spanish needles, and rattlesnake root or tall white lettuce.

SHRUBS OR TREES.

January to May—Manzanita, of California, and willow, of California.

February to June—Gall berry, of the South.

March—Orange, of the South.

April—Box elder or ash-leaf maple, red or soft maple, poplar or aspen, silver maple, and Judas tree, of the South.

April and May—Willows (also trees) and Judas tree, of the South.

May—Shad-bush, alder, maples, sugar maple, crab apple, hawthorns, fruit trees—apple, plum, cherry, pear, etc., currant and gooseberry,—wistaria vine, of the South, Chinese wistaria vine, of the South, Japan privet, of the South, varnish tree, of the South, acacia, of the South, black gum, of the South, bladder-nut, persimmon, of the South, saw palmetto, of the South, and buckeye.

May and June—Barberry, grape vine, tulip tree, sumac, buck thorn, of the South, and black mangrove, of Florida.

June—Magnolias, of the South, honey locust, wild plum, black raspberry, locusts, and red raspberry.

June and July—Blackberry, and sourwood, of the South.

July—Button bush, basswood, and Virginia creeper.

June and July—Cabbage palmetto, of the South.

July—Blue gum, of California, and catalpa.

July and August—Pepper tree, of California.

July to September—St. John's worts.

August—Late sumac.

August and September—Indian currant or coral berry.

August to Frost—Red gum, of California.

August to December—Japan plum, of the South.

August to January—Germander or wood sage.

The Season in England.—Mr. A. Pettigrew gives the following very doleful account, in the *Journal of Horticulture*, of the condition of bees in England, on account of the cold weather and frosts in the early spring:

In the changing and uncertain climate of Great Britain showers and falls of snow are not uncommon in the month of March, and sometimes we have had such in April. Experienced bee-keepers know that while snow is on the ground or around an apiary, bees should never be allowed to leave their hives. During frosty weather they will not venture out, but when the thermometer rises and snow begins to melt, the bees venture to fly, and in doing so many perish. They seem to be dazzled and bewildered by the light, and rapidly fall into the snow, and become motionless in a moment. The heat of their bodies melts soft snow, causing them to sink about an inch in it. When snow is crusted on the surface, bees, on touching it, lose the power of their feet and legs by a kind of paralysis, and many of them are unable to take wing, roll on to their backs, and speedily perish. Many colonies are weakened—some are destroyed by loss of bees in snow. This is well known.

The severity of the present frost, and its continuance in the middle of March, is a new experience to British bee-keepers. The past winter was mild and favorable for bees. At the end of January colonies were strong, and the bees of many of the hives in this section of the country began to breed; then when snowdrops and crocuses came into flower, the bees in great numbers were seen on them. Some of the strongest colonies had two and three seams of brood sealed, and doubtless much brood unsealed. At the beginning of March we had several days of cold and cutting winds, so cold that bees would not leave their nests for food; afterwards severe frost set in, bringing down the

mercury of the thermometer at nights below 20; one morning, the 10th of March, to 13, or 19° of frost. Snow fell in Cheshire on the 16th of March. If the frost had come a month sooner, little harm would have been done to colonies.

In my time we have never before experienced such severe and continuous frost in the brood-rearing season, and therefore I cannot speak from experience as to the extent of the injury probably done to the brood. We know that bees dislike cold winds even in April and May, and in order to protect their brood then from chilling winds, they contract their doors with compact masses of their own bodies. In the months of April, May and June, bees spread the eggs of their queens as widely as they can be covered and hatched, and when cold winds come, they endeavor to keep them out by blocking or corking their doorways. In cold weather bees are very helpless creatures.

In winter and early spring bee-masters will do well to give them all the protection possible. Before the present frost set in colonies were in capital condition, and fruit trees covered with blossom buds, giving bee-keepers good hopes of early swarms and great results, and therefore this severe and unexpected weather is the more disappointing.

Sweet Music.—All of the following songs and piano pieces come to us, in a package, sent by the well-known publishing house of Oliver Ditson & Co., Boston.

Very many ballads of the "Lilly Dale" order have, of late years, been given to the public, but very few of them have such smooth, beautiful music as that which belong to the song "Under the Willows," by C. Connelly. Another charming musical tid-bit by the same author is "That first little kiss he gave me," an artistic song and dance in the play of "My Sweetheart."

Still another beauty is "Sleep, Baby Sleep!" a charming lullaby by Angelica McConn Fellowes. "The Train," by Molloy, is a song of our hurrying time, and "Oh, that I had wings," by Havens, will sound well in church. "Emmy Polka," by Granada, is one of the pieces played by the Spanish students. "Heart and Hand Waltz," by Le Baron, is a good arrangement. "Sunshine Polka," by Ida Hurley, is a pretty piece of brightness.

 **The Biographer**, is the title of a new serial, the first number of which is on our desk. It is published at 23 Park Row, N. Y., and, of course, it is illustrated with engravings of the persons whose biographies it contains.

This initial number has 25 biographies, comprising some of the most prominent persons of the present age. We welcome this new candidate for popular favor; it will make an exceedingly valuable book of reference.

"Homicide and Suicide, in the city and county of Philadelphia, Pa., during a decade, 1871 to 1881, inclusive," is the title of a pamphlet laid on our desk "with the compliments of the author." John G. Lee, M. D., Coroner's Physician. It contains many interesting incidents and considerable statistical information.

New Mexico Celebration.—We have received an invitation to attend the Tertiary-Millennial (third of 1,000 years) Anniversary Celebration, including a comprehensive Mining and Industrial Exposition, of and for the Rocky Mountain region, which will be held at Santa Fe, New Mexico, July 2 to Aug. 3, 1883.

It will present the characteristics of the three civilizations which have occupied New Mexico and the adjacent territory, since its first occupation by the Spaniards, in 1550, to the present time, and illustrate the progress of the several centuries.

It is said that the first European who ever visited the region now known as New Mexico, was Cabeza de Baca, who was wrecked off the coast of Texas in 1531. He was struck with the appearance of the country, and in 1541 returned with an expedition headed by Coronado, and, as nearly as can be ascertained, some of the party settled at Santa Fe in 1550.

Frank Cushing, who created so much interest in the East, last summer, with a party of Zuni Indians, will have quite a large band of them at the Santa Fe Tertiary-Millennial Celebration, with a large collection of curious things manufactured by them. This will prove one of the special attractions.

We should be delighted to attend this grand celebration, but shall be unable to do so.

 We have received a small tin can for honey, from Mr. W. M. Hoge, of London, England, such as are now being used extensively in that country. The cover fits tightly on a flange, and can be easily and instantly pried off with a nickel, but cannot be knocked off. Its large mouth makes it very suitable for candied honey.

CORRESPONDENCE

For the American Bee Journal.

How the Bees Have Wintered.

G. M. DOOLITTLE.

By turning to page 741 of the BEE JOURNAL for 1882, the reader will see how a part of my bees were left on their summer stands to winter, and a part were put in the "bee cellar" there described.

We have had it very cold here for the past two weeks, till within a day or two. On the morning of April 30, Skaneateles Lake (16 miles long and 2 miles wide) was frozen over nearly the whole length of it; the mercury standing at 18° above zero. As is my custom, I examined the bees that morning, looking in every hive, and counting the spaces that the bees occupied between the combs, as well as to see that all had sealed honey. The examination showed that out of the 43 wintered on the summer stands, 11 were dead; 5 of which had died since the past cold spell commenced. Of the 32 left, 10 were good, strong colonies, 10 fair, and the remainder weak. Of the different methods tried, those having the full entrance left open, and a little upward ventilation through two quits, with the cap to the hive packed with chaff came out the best. These, also, had a board stood up in front of hive to keep out the snow, and to prevent the wind from blowing in at the entrance and the sun from shining on the same. The next best were those having full entrance and enameled cloth over the top; and those having a little lower ventilation, and a plenty of upward, the poorest of all. The colony having the Texan queen was the first to die, but as I have two other queens from the South (one from Louisiana, and one from Georgia), which, with their bees, came through the winter in splendid condition, I think that the climate in which queens are reared has little, if anything, to do with their wintering qualities. The best colony, of those wintered out of doors, is the one having the old Palestine queen, which numbered 8 good, full spaces of bees, while 7 is the highest of any besides.

Having described those wintered out of doors, I will next speak of those wintered in the cellar. There were 37 full colonies put in, and a few queen-rearing nuclei, as an experiment, which was not counted last fall.

Of the few nuclei, about one-half died; the temperature was not high enough for mere a handful of bees, as this was about what each one was. The thermometer marked 42° in the cellar during all the winter, after it became settled, and I think, if it could have been kept at 52°, these little clusters of bees might have wintered quite successfully. As elm and soft maple were in bloom on April 14

to 18, the bees were put out, and, of the 37, all were alive and in good condition except 3, which were rather weak. They gathered pollen at once, but the cold spell put a stop to operations, and also showed that we are not always sure of warm weather when pollen becomes plenty. By referring to page 741, as above, it will be seen that I left the entrance to a part of those put in the cellar, as on the summer stands, a part with full entrance, a part raised on $\frac{1}{2}$ inch blocks, and the remainder raised on inch blocks. Upon examination, the other morning, I found that those having small entrances occupied, on an average, 5 spaces, and the bottoms of the combs were quite moldy. Those having the full entrance open averaged 6 spaces, with a little mold on the combs. Those raised on $\frac{1}{2}$ inch blocks, averaged 7 spaces, with the combs nice and bright; while those raised on inch blocks, averaged but $5\frac{1}{2}$ spaces, yet the combs are free from mildew. The three weak ones are all among those having the small entrances. It will also be seen, by referring to page 741, that the bees were to be put in at four different times; as the weather became suddenly cold about Nov. 22, those that were to be put in Dec. 1, were put in without further delay, so that I did not carry out that part of the experiment as I intended. After those were put in on Nov. 3, the rest had a fine flight on Nov. 10; while those put in last, had a snow storm on them, with some cold freezing weather, but after careful watching all winter, and the above examination, the difference is not enough to favor either, early or late setting in. Toward the latter part of the winter the cellar seemed to become quite damp, which appeared to effect the nuclei; but as far as I could discover, the full colonies were not injured thereby.

As the past winter has been a very severe one, I think that I am better prepared to winter successfully than I was last November. Especially do I recommend raising each hive on $\frac{1}{2}$ inch blocks, when wintering in the cellar. This seems to allow all the moisture to pass off, so that the bees are kept quiet, and the combs clean and bright.

Regarding out-door wintering, my loss has been so great that I am hardly entitled to an opinion in the matter; yet, from past observation, I shall try largely, the coming winter, a full width entrance, with a little upward ventilation through two or three quits, covered 4 inches deep with chaff; no holes left open in cover, as I believe all that is needed is what air can pass through the cracks at the top of the cap.

I should have said, in my last article, regarding stimulating in the spring, that about the first of May, according to the season, all colonies not having 2½ frames of brood were shut up by means of the division-board, etc. In this unfavorable spring, to begin so early would do no good, for the best colonies in my apiary do not have enough to amount to one full frame of brood.

Borodino, N. Y., May 2, 1883.

For the American Bee Journal.

Wintering Bees in Cellars.

H. V. TRAIN.

Mr. J. B. Miller, of Mechanic Falls, Me., asks, on page 138, of the present volume of the BEE JOURNAL, that some one, who has wintered bees successfully in cellars, should give plain simple directions how to do it."

In December, 1883, I purchased two colonies of bees, in boxes, and moved them 20 miles on a sled; since that I have wintered bees every winter, save one. For the first five or six years I experimented in a variety of methods, and lost more or less every winter, and it was usually more. Then I commenced cellar wintering, and have never lost 5 per cent. in any one winter since; and for the last five years I have not lost 1 per cent. in any one winter; and I have wintered from 125 to 155 in the one cellar each year. I have become so confident of success that I would not give 1 cent per hive to have them wintered safely through any winter, cold or mild, provided they are in normal condition in the fall.

If any man wants to winter bees on their summer stands, in clamps, in caves, in dark bed-rooms, in old houses, or in straw piles, I have no advice to give. I have experimented in these to my sorrow; and if any of my friends ask me for advice about wintering bees any where, save in a good cellar, I can only say: "Don't." This, of course, applies only to our climate.

My cellar is under the main, or up-right part of my house; and is 18 by 28 feet, and 7 feet high. There is also a cellar under one wing (the kitchen) 16 by 26 feet, separated from the bee cellar by a wall, and connected with it by a door. The last named cellar is used for family purposes, and we pass through it, in going to the bee cellar, when it is not proper to open the outside door. The bottom of the cellar was very dry sand, and is made firm by the use of pounded stone, and smooth by quick-lime plaster, so that water will disappear very rapidly when poured upon it. I set my hives four deep, directly on the top of each other, and a little apart, so that I can, if need be, take down any one tier and not disturb any other tier. The hives are set facing aisles 4 or 5 feet wide, so that I can pass down the aisles with my small bed-room lamp and see all the entrances at any time, day or night; which I always do from two to five times every 24 hours.

To prepare them for the cellar, I take off the enameled cloth and all the cushions, and put in their places, a piece of porous cloth, or, what I like better, a piece of matting from tea-chests (they cost nothing, when I can get them), and put the cover directly on this; which makes upward ventilation enough for a cellar. My thermometer hangs on a post, midway of the cellar, and about half-way from the floor to the ceiling. I never allow it to fall below 40°, and never rise above 50°, if I can control it; but I

would rather for it to rise above 60° than fall below 40°. Below 40° means dysentery or death, in my experience. The cellar is always kept perfectly dark; and the bees are never disturbed unless it becomes absolutely necessary.

To ventilate the cellar, there is a tin pipe 4 inches in diameter, extending from near the bottom of the cellar to near the point where the pipe from the sitting room stove enters the chimney, and there enters the chimney. The tin pipe is made air-tight through its whole length, and air-tight where it enters the chimney, so also is the stove-pipe; so that when ever there is a fire in the stove there is a heavy draft out of the cellar, and we always keep a fire in the stove when the bees are in. I consider this draft an essential condition.

My last improvement in letting air into the cellar, is a box made of four boards, 16 feet long and 12 inches wide, nicely made so as to be water-tight, with both ends open. This forms a pipe 10x12 inches inside. One end of this pipe is fitted into a window so as to admit no light. The other end extends 16 feet into the cellar, and is raised about a foot higher than the end in the window, so as to carry all the water from the melting ice out of the window. At the outer end of this pipe there is a gate by which it can be partly or wholly closed at pleasure. Whenever the weather is warm, this pipe is filled nearly full of ice or snow its whole length, so that all the air that enters the cellar comes over and among blocks of ice for 16 feet, which affects its temperature materially. Over the inner end of this pipe I hang a black curtain to exclude all light.

I have often contemplated the feasibility of a sub-earth pipe to act in conjunction with the ice pipe, so as to let the air through either at pleasure. I think it would make a perfect arrangement, but have never tried it for want of strength to dig or means to hire. With my present arrangement I have no trouble unless I neglect some of the following rules:

1. Keep the bees breeding late in the fall, by feeding if necessary, and have them well cushioned, the entrance partly closed, and otherwise kept warm.

2. Put them into the cellar early, before any frost gathers on the honey, to crack the cappings.

3. Watch very carefully, and never let the thermometer sink to 40° (it had much better never come below 44°), and never let it rise above 50°.

To cool off the cellar, when the weather outside is colder than 40°, let in as little air as will keep the bees alive, and keep ice in the pipe. When the cellar gets too cold, shut off the air, and, if necessary, carry in a kettle of coals from the stove. This last is a good practice, whenever it can be done and not make the cellar too warm.

4. Never take the bees out until they can get pollen, unless it is for a flight, and then put them back the same day. I never take mine out unless they get the dysentery, and then

only the sick ones, and have never done that but a few times, with a few.

5. Exercise good common sense, and you will have no trouble.

I have now 131 colonies in the cellar and two nuclei. They were put in Nov. 13; and, up to this date, they have not made any noise that could be heard 10 feet from the hive, excepting one colony, which was inadvertently set under the ingress pipe, where the cold air fell almost directly on it, and they took the dysentery early, and I tried the carbolic acid and sugar; it seemed to check it for a time, but they are noisy again, and I shall give them a flight the first warm day. All the rest are in fine condition, thus far. The thermometer marks 48° this evening, and all is quiet along the whole line.

I will close by saying to all the wise ones, that, in my opinion, if their bees never get any sour honey, they will never have dysentery; and I do not care how much pollen they have, either. If any doubt my statement or opinion, let them carefully examine every hive that has the disease, and see if they do not find sour honey, if they find any. Mind another thing, if in cellar; the honey outside the cluster gets cold enough to condense the breath of the bees; that honey will almost always sour, more or less, and give dysentery.

Mauston, Wis., March 17, 1883.

Western Missouri Convention.

The Western Bee-Keepers' Convention was held at Independence, Mo., April 28. Jas. A. Nelson, of Wyandott, Kans., president, on taking the chair, said:

GENTLEMEN:—I am glad to meet so many bee-keepers on the present occasion. I have nothing of special importance to offer, but think the wintering problem deserves attention, and will give you some items of my own experience.

I put into winter quarters 66 colonies on the summer stands, all but 11 of them in Langstroth hives, and nearly all of them had chaff cushions, 6 or 8 inches thick in the upper stories; I have lost 8 colonies in all, 3 in Langstroth hives, and 5 in hives having deeper frames. A few weak ones are still among them, and since the first of April, some of the strongest colonies have dwindled, and one has superseded the queen. The young queen was fertilized and laying on the 20th inst.

Another matter—small, it may be, but bee-keeping is made up of small matters. I notice that many persons do not save the bits of comb which are necessarily made about an apiary. The demand for beeswax is great and increasing, and it behooves us all to save and produce all we possibly can. It is no great trouble with a wax extractor to place the bits of comb into it, and when once full, to heat it and let the wax run into a pan placed to hold it. A wax extractor will soon pay for itself in the amount of wax that might otherwise be allowed to go to waste.

The question is often asked, "Will it pay to use foundation at present prices?" I answer yes—in an ordinary season it will pay to use it even at a cost of \$1 per pound, or to use wired frames filled with it, even if they cost 25 cents each. I have proven it by actual experiments in my own apiary.

In thanking you for the unexpected honor of being elected president of this association, allow me to express the hope that our present meeting may be pleasant and profitable to us all.

The members made individual report on wintering, as follows:

NAMES.	Size of Frames.	No. of Colonies Fall, 1882.	No. of Colonies Spring, 1883.	Where Wintered.	Pounds of Honey Consumed.

Mr. S. W. Salisbury, secretary of the convention, read the following paper:

Mr. President and Members of the Western Bee-Keepers' Association:

On fixing the time for our semi-annual meeting, which has now arrived, our members generally shared the desire to learn from each other how their bees had passed the winter, and how well prepared they were for active summer work.

In this latitude I am confident that bees winter best on their summer stands, especially if they are protected with a mat or quilt over their frames, or with a piece of burlap or carpeting that will keep the chaff or leaves, which should half fill the upper story, from getting between the frames. They must, however, in any situation have plenty of food, and I am confident that 20 pounds of honey is the least possible amount that will safely bring a colony through winter and the first two months of spring. Where bees can have an opportunity to fly every month, and generally several days during each month, as they usually do in this latitude, I think it must be obvious that bees will suffer less by natural frosts than by confinement in a cellar.

But an unusually severe winter, with long continued cold, will necessarily produce damaging effects upon bees on their summer stands. Let the thermometer stand at zero, or thereabouts, for two weeks at a single time, and chaff hives are insufficient protection. Let this cold be continued for 30 or 40 days without interruption, and every colony must suffer, while a large percentage will be ruined. An occasional mild day, which, without inducing bees to fly, enables them to move among the frames and replenish their stores for

present use from different parts of the hive, tides them over another cold spell and enables them, with health and vigor, to greet the invigorating rays of the sun on every salubrious day of the winter solstice. In colder latitudes, cellar wintering must be preferable; in warmer latitudes cellar wintering would be intolerable.

Every bee-keeper has his own fancy for hives. Every novice in bee-keeping tries to invent some new arrangement for a hive superior to all others. Not long since such an inventor exhibited to me a device to prevent drones from building drone comb, which he declared with great sincerity and earnestness to be wholly his own. He positively affirmed he had not got the idea from any book whatever, and extorted from me the promise not to make public his device until he had obtained a patent. In imagination he could see millions in it, notwithstanding he is the only person in the world who ever knew of drone bees making any comb at all.

But nearly every bee-keeper, in some easy or natural way, becomes attached to some particular kind or form of hive, and as he makes the business a specialty disposes of or discards others and develops his favorite kind. We thus see nearly every prominent apiarist in the country (all, however, with movable frames) using a different style of hive.

The Langstroth, undoubtedly, has the call at present, being exclusively recommended by several prominent bee journals, but I very much doubt its general adaptation or desirability. The length of its frame, 17 inches, and depth only 9 inches, makes it objectionable for successful wintering and springing of its inmates. It is undoubtedly too large and barn-like. Going between that and the American frame, I have found, by an experience of 20 years, that a similarly constructed frame, 14 inches long and 11 inches deep is best.

Little attention is usually given to the ventilation of hives, especially in summer. Not unfrequently the front of a hive remains for weeks covered with bees while they hang in festoons from the bottom board, and all for the want of ventilation. Let a hive, thus covered, be raised one-quarter of an inch from the bottom board, and kept so raised by blocks under its corners, and every one of this idle crowd will go inside the hive or into the fields to work in less than a single hour.

It's a mistake to say that bees cluster outside the hive for the sake of swarming. They never stop work for that purpose, but when they cannot sufficiently ventilate their hive to prevent danger of their comb melting down, they have sufficient sense to go outside, and thus save their stores.

One of the most provoking, and probably the most fatal malady among the bees, in this locality, is dysentery. We know its effects, but we can only guess at its cause. To say that it has diminished numbers, or cold weather, or impure honey, does not satisfy the anxious inquirer; for some colonies in the cellar are afflicted with it, and as the sick ones die, of course their num-

bers diminish; while the claim that impure honey causes it, is answered by the fact that other colonies, feeding from the same source of supply, are not affected in the least. I would suggest faithful inquiry and observation among the members of this association as to the real cause or causes of dysentery among our bees and the resultant remedies for the disease.

It is always noticeable that some colonies build up and increase much faster in the spring than others. To have them all full of bees and ready for the honey harvest is the great desideratum of the apiarist. The most prosperous colonies, early in the month of May, can suffer the loss of a frame of brood without apparent injury, while the impetus, energy and strength given to a weak and struggling colony, by the insertion of such frame, is almost wonderful.

I deem it of the utmost importance to have every colony in an apiary as nearly equal, both in stores and bees, by the middle of May, as possible, and this equality can easily be effected by the interchange of a few frames between them. Of course all queenless colonies should be supplied with queens before this time, and weak ones united.

The question as to how many bees can profitably be kept in one place is not readily determined. I see it noticed that in some parts of Germany several thousand colonies are frequently found in a single compact neighborhood, while in this country the weight of authority seems to place a much smaller limit to the number that can profitably be kept in one locality.

Let us, if possible, add something to the solution of this question at our future meetings.

Since brimstone has, in a great measure, been discarded, the question of increase enters seriously into the calculations of the bee-keeper.

How to overcome the great disasters of winter and spring without detriment to the crop of honey? If he works for increase he can obtain no surplus honey, and consequently no revenue, as the demand for colonies is limited and prices very unsatisfactory.

The natural tendency of bees is to swarm, not only once, but twice or three times. The parent colony is thus left without workers, and can produce no surplus. The second and third swarms are often too small to obtain a livelihood until the coming spring, while the first swarm can only furnish a small amount of honey to the bee-keeper. He must, therefore, restrain swarming, and keep his forces united in order to obtain the best results.

As time for swarming approaches, I remove two frames of brood and bees from each of the most prosperous colonies, being very careful not to take the queen, and uniting eight of these frames in a single hive, thus construct one-fourth as many new colonies as I have in my apiary. By giving these new colonies a queen-cell ready to hatch, I soon have this number of full and prosperous colo-

nies, all capable of collecting surplus stores. The old colonies being furnished with frames of foundation, have such additional work to perform that in a majority of cases they forget to cast a swarm that season. Such swarms, however, as do issue, I furnish with two or three frames of brood from the hive whence they came (first removing all queen-cells therefrom), and then place them on the old stand. The parent colony I at once break up into nuclei for queen rearing, or unite the frames with others into full colonies.

Other questions readily present themselves for consideration, but I desist, with the remark that it is probably a good thing that we do not all think exactly alike.

The discussion which followed was based mostly on points made by the essayist.

L. W. Baldwin says he prefers cellar wintering. He placed 207 colonies in the cellar the 1st of December, and wintered every one. He returned them to the summer stands on the 1st of March, and found, by weighing, that they had consumed only five pounds and one ounce of honey each; while out of doors they would have consumed ten or twelve pounds each.

J. D. Meador prefers small frames of 10 or 11 inches depth; he would not use the Langstroth frame; he thinks bees prepare themselves for swarming by quietness and fattening; he thinks bees on summer stands must have the sun to shine on their lives in winter; he lost heavily this last winter of such colonies as he did not properly prepare for winter.

P. Baldwin says bees prepare for swarming by clustering and resting, and that they will do so inside of the hive and in boxes if not on the outside; he does not want foundation nor old combs for swarms. His bees do best in making their own comb.

D. G. Parker wants foundation to prevent excess of drones, if for no other purpose, because bees construct drone comb largely, especially in swarming time.

The 20th day of September was designated as the time, and Independence as the place for holding the next convention. Committees were appointed to prepare premium lists for said occasion, and to make arrangements for a two days' session.

Thanks are extended to Mrs. J. D. Meador for providing a sumptuous collation, which was served in an adjoining room in the court house, and heartily relished.

Sundry other miscellaneous business was transacted and convention adjourned. S. W. SALISBURY, Sec.

The Southwestern Iowa Beekeepers' Association will hold its annual meeting at the apiary of L. E. Mercer, Lenox, Taylor county, Iowa, May 26, 1883. Meeting called at 10 o'clock sharp. Forenoon: Election of officers. Afternoon: Work in the apiary, when any question, with regard to handling bees, will be practically explained. Accommodations will be provided for visitors from a distance. W. J. OLIVER, Sec.

Burying Bees in Clamps.

BENJAMIN FRANKLIN.

In the BEE JOURNAL, page 177, is an article by Mr. Wm. Bradford on clamp wintering and ventilation. On April 19, I visited two box-hive men who both wintered their bees as described in the first part of Mr. Bradford's article.

One of the men is very old, and has kept bees for a number of years, always with success, whenever he has buried his bees. He showed me the places where they wintered last winter. He had taken out 12 colonies the day before I visited him, and the bees were flying out of the hives and carrying in pollen, and were very strong. The hives were clean and not "spotted," in the least; the combs were all clean and bright, with plenty of honey. He winters about 10 or 12 colonies in a place.

After packing straw around the hives, he puts straw on top, then some dry dirt on the tops of the hives, then covers over with boards to keep out the wet; then covers all up with earth, 3 or 4 inches deep. The hives came out as dry as when put in. He gives no upward ventilation; the hives are sealed up as tight as the bees can do it. There is a hole in the side of the hives, 5 or 6 inches from the bottoms. The hive sets upon a 4x4 joist, in the bottom of trench. He puts straw or buckwheat chaff on the bottom. He said, one fall, he had 100 colonies of bees; he put them in on Oct. 1, and they remained there until April 1; when he took them out they were in fine condition, without loss. Some of the colonies were very small, but they came out with plenty of bees and honey.

He covers up his trenches with boards, and that saves digging new trenches every fall. He cleans out the straw sometime before he wants to put the bees in, and lets them dry out. It does not take a very large place to bury 100 colonies. It saves carrying them in the cellar, and is not half the work that it is to pack them in chaff.

I shall have him help me bury some of mine, next fall, if all is well. I have tried almost all kinds of ways, but lose some in any way.

I thought I would write this, and, perhaps, it might give some light on the wintering subject. Some may think they are right, but when they test their ways of wintering, year after year, they may fail in some years. This man told me he heard so much about wintering in chaff, that in the winter of 1881-82, he packed all of his in chaff, except 5 or 6 which he buried, and these were all he had left for seed. One of his neighbors, who had buried his bees, in other winters, thought he would let them go that winter, and lost them all (some 80 colonies); all the man had to depend on for a living, and an old man at that.

One of my neighbors winters his bees, packed in chaff. He uses an extra box, and sets the hive in the bot-

tom. There is about 1½ inch of space under the frames; the entrance is 4 inches long and ¾ high; he leaves the quilts on, the same as he puts them on after taking off the surplus boxes. The bees wax them down as close as they can; he has nothing over the frames, and does not cut holes through the combs. His bees come out good.

In the year of 1881-82, when I lost 75 colonies, his came out without loss. There was no chance for upward ventilation, for the quilts were all covered with propolis, and waxed tight to the frames.

Franklinton, N. Y., April 30, 1883.

For the American Bee Journal.

The Standard Langstroth Frame.

G. M. ALVES.

Mr. James Heddon, on page 224 of the BEE JOURNAL, advocates 17¾ inches as the proper length of the Langstroth frame, on the sole reason that it is so given by Mr. Langstroth, in his book published about 20 years since. Now, I submit four propositions why 17½, and not 17¾ inches, should be universally accepted as the standard length.

1. There are more Langstroth frames in use of that length than any other.

2. The largest manufacturers of hives, and the greatest number of them, have adopted this size.

3. This size will exactly take eight standard one-pound sections—a very important consideration with those who prefer to take their honey in frames.

4. The editors of the principal bee periodicals have, and do now, give this size as the standard, and on the authority of the Editor AMERICAN BEE JOURNAL, Mr. Langstroth himself has approved the change. See AMERICAN BEE JOURNAL for 1882, page 251.

Now, if these propositions are all true, and Mr. Heddon cannot successfully disprove them, the conclusion to all who appreciate their weight is, that the standard Langstroth frame should be, and is 17½ inches in length.

Now, in the light of the above, I must submit that Mr. Heddon, in selling and advocating a frame 17¾ inches in length as the standard Langstroth frame, is in this particular detrimental.

Henderson, Ky.

[As stated by Mr. Alves, in 1878 we referred this matter to Mr. Langstroth, and he replied that he now considered 17½ the correct measurement for the length of the standard Langstroth frame. See BEE JOURNAL for 1878, page 427. As Mr. Alves remarks, the fact that this size of frame is better adapted to the use of cases to hold 8 small sections, should be very potent in deciding the point in controversy. This small difference often makes serious trouble.—ED.]

For the American Bee Journal.

How to Press and Mount Flowers.

F. A. HUNTLEY.

In reply to Mr. N. Z. Hutchinson's inquiry in the BEE JOURNAL of April 25, asking how to press and mount flowers for study, I will give the method by which the students of the Iowa Agricultural College make up their herbariums.

In the first place the collector should have everything in readiness for collecting, pressing and mounting his specimens before he begins the work. The tools and apparatus for collecting consist of a good sharp pocket knife to be used for cutting and trimming, a gardner's trowel, or a good strong butcher-knife for digging, as it is sometimes advantageous to have a portion of the root with the flower, and a botanizer's can, or some other convenient vessel, for carrying the plants and keeping them from the dry air and sun. The collector will find it greatly to his advantage to have a good pocket lens with him, to enable him to examine more closely the various parts of his specimens. He should have a note book in which he may note down anything that he might want to look up, at some other time; and if he wishes to classify his specimens while out, he should have a good classifier's manual with him. The one used here, and probably the best in the United States, is the one edited by Dr. Asa Gray, the well-known professor of botany in Harvard University. It is always easy to classify specimens while they are fresh, as all parts may then be easily discerned.

The apparatus for pressing consists of two wide boards, about 12x18 inches; these should have cleats nailed on them, to keep them from warping, and to keep the lower one up from the floor, so that no dampness will contract about the press.

The pressing paper should be thick and reasonably soft in texture, so as to be a good absorbent. The paper sold for putting under carpets is about as good as can be procured. Tissue paper is the best for keeping the specimens from direct contact with the drying paper. All the paper should be cut to fit the press. In placing the plants in the press, great care should be taken to arrange the parts, as to the position they are to have after mounting; the leaves should be so arranged as to show both upper and under surfaces. Where a portion of the root is to be saved, it is best to cut one side entirely off, so as to avoid unevenness in the specimen.

The amount of weight to be applied to the press should be enough to flatten the specimens without crushing. Driers should be changed twice a day and placed in the sunshine, or near a fire, so that they may be thoroughly dried before exchanging them for the damp ones in the press.

The value of a specimen depends upon the rapidity and care with which it has been dried. Therefore, the press should always be kept in a dry

place. When the specimens have become thoroughly dried, they should be mounted on white paper and labeled with the name of the order, genus, species, and the common name, if it be known; any other information may be placed upon these labels, which will help to identify the specimens.

The mounting paper used should be a good article, smooth, stiff and firm; and, according to Dr. Gray's directions, should weigh about 28 pounds to the ream of 480 sheets. The size of the herbarium sheet adopted in the United States, is $11\frac{1}{2} \times 16\frac{1}{2}$ inches. Paper may be procured from a bindery or ordered by any stationer; a good article should cost about a cent a sheet.

The specimen should be mounted about the centre of the sheet, and the label placed in the lower right hand corner. The label should be not larger than $1\frac{1}{2} \times 3$ inches, and they may be partly printed, if the collector so desires.

For fastening the specimen on the herbarium sheet, common white glue, dissolved in just enough acetic acid so that it may be easily applied with a brush, has been found to be the best for all ordinary plants.

As the specimens are mounted, the sheets may be laid away in a binder or a good clean box made of tin or wood. A good home-made binder is made by taking card-board and cutting it a trifle larger than the herbarium sheets, and making a hinge of cloth on one side, and with strings to the other side, and ends of the cover with which to tie the sheets in.

The herbarium should always be kept in a dry place, so that no mold will collect on the specimens and destroy them. Sometimes the herbarium is attacked by insects, which are very destructive, and especially is this so with honey-bearing plants. To effectually destroy these pests sprinkle the specimen with a mixture of alcohol and corrosive sublimate.

Agricultural College, Ames, Iowa, May 2, 1883.

For the American Bee Journal.

Jasper County, Mo., Convention.

In pursuance of a call heretofore issued, about 25 bee-keepers assembled at the office of Ira Creech, in Joplin, Jasper County, Mo. The meeting was called to order, and Dr. J. T. Bruten chosen chairman, Ira Creech secretary. The chairman stated the object of the meeting, after which a general discussion was entered into by Bruten, Holden, Creech, Kemmerdiener, Mrs. Gaston and others, upon the best way to handle bees, which brought out the ideas of the various bee-keepers present in regard to hives, artificial and natural swarms, and various other items connected with the apiculture; after which a permanent organization was had, which was named the Jasper County Bee-Keepers' Association.

Officers elected for the first year: Dr. J. T. Bruten, President; S. B. Holden, Vice-President; Ira Creech,

Secretary, and J. S. Reding, Treasurer.

Committee to draft by-laws, J. S. Bruten, John Nilson and E. Kemmerdiener. The next meeting to be held in Joplin. A regular meeting is to be held on the first Thursday in each month.

It is designated that the meeting be held in different places in the district, so as to accommodate all who are interested in apiculture.

Resolutions adopted that the *Kansas Bee-Keeper*, Columbus, Kansas, and the *AMERICAN BEE JOURNAL*, Chicago, Ill., be furnished with a synopsis of the proceedings of this meeting. Adjourned. J. S. BRUTEN, Pres.

IRA CREECH, Sec.

For the American Bee Journal.

Cure for Foul Brood.

JOHN DUNN.

The following I have copied from the *Desert News*, from the pen of W. A. & P. M. Greggs, of Payson, Utah:

"The plan we adopt for the destruction of this fatal disease (viz.: foul brood) among bees, is as follows: When we discover a colony affected by this disease, we find the queen and cage her. We then remove the affected hive and replace it with a box painted the same color as the hive. We next brush the bees off the combs into this box, and allow them to stay there 48 hours. The caged queen is then put in the box with the bees, and is kept caged 48 hours. There should be no frames or combs put in the box during this time, but a few sticks may be put in for them to work upon. When the bees are brushed off the combs, the combs should be immediately destroyed, also the hive. While staying in the box the bees should not be confined, but allowed to fly out freely, so as to cleanse themselves outside the hive, then they will not besmear each other.

At the expiration of 48 hours the bees should be transferred to the hive, which is designed for them to occupy. This hive should be filled up with frames with foundation in them. The queen is now liberated, and the bees are now cleansed and ready to go to work like a new swarm. If a frame of brood is given them, it will be better and safer, as they will not then desert the hive. This remedy has been used for five years with success, and never known to fail. It will only apply during the honey season. If foul brood is discovered in early spring, before the honey season, or in the fall of the year, after the honey season, we know of no remedy but destroying bees, hive and all."

Since the 29th of March bees have not been out much; it has been snowing and raining most of the time, so that a few colonies have perished. I have been able to keep my bees in good condition. I have found one of my colonies queenless (hybrids), so I have given them a frame of eggs and brood, so that they can raise an Italian queen, as I was not sorry that the old hybrid queen was gone, only I

did not want it to take place until I had a good queen to give the bees."

Tooele City, Utah, May 2, 1883.

For the American Bee Journal.

That "Three Ring" Fancy.

W. H. SHIRLEY.

On page 236 of the *BEE JOURNAL* for May 9, 1883, Mr. James Heddon, in his reply to W. Z. Hutchinson, on "Best bees; how obtained," puts me down as a "ring" fancier, but fails to give my way of "ring" or band breeding. The rings I anchored so long ago, are these: First ring, good honey gathering; second ring, good-nature; third ring, to get rid of that hybrid cross "cross" and strained mixed-up mess.

Yes; I have a fancy for the golden rings, but it must be backed up by the ring of pure gold, and I shall try hard to breed up my apiary of 100 colonies, so that they will be all alike, as near as possible. No two kinds of hives, or two kinds of bees for me! And the bee I am after is the one that will produce the most honey, whether black, brown or blue; three rings or no rings.

I took my first lessons of bee-keeping from Mr. T. F. Bingham, for four weeks, in 1876. That four weeks of practical knowledge has been worth many dollars to me, and to those about to take up bee-keeping as a business. I would say, go and spend a season with some practical apiarist, regardless of cost; after that, subscribe for some good bee-paper and you will then feel master of the business. As a teacher I know of none so well fitted in every respect, as my esteemed friend, James Heddon. I speak from experience. "Honor to whom honor is due."

Glenwood, Mich.

For the American Bee Journal.

The Standard Frame, Etc.

D. F. MARRS.

There seems to be a move among bee-keepers to adopt a standard frame, which I believe to be a grand idea. I have been making my hives, this spring, of the Simplicity, two-stories high; but as Mr. Heddon says some have different sized Langstroths, and by comparing his figures with my frames, I find that my frames are $\frac{1}{4}$ inch too long. This I very much regret, for I have quite a number of hives made, but I made mine by the instructions laid down in Root's A B C Book.

My bees are just "on a big tear;" I have had 8 swarms already—some of my colonies have swarmed twice; my first swarm came out April 6th; the next on the 9th or 10th. I have 16 colonies spring count, two are weak; they are all hybrids, or mixtures of various grades, from the black to a bright yellow.

I only lost one in wintering, and it starved through lack of attention. Such a thing as wintering bees in a

cellar is unknown here, only by reading of it in the papers.

What swarms have issued are the largest I ever saw. I hived the last and largest one, as usual, in the lower story only of the 9-frame Simplicity Langstroth hive, and it lacked about a quart of holding all the bees after they got on the frames. Probably I should have divided it into two, giving one an extra queen; but I just set on the other story, raising the duck on top of the other frames. The bees are gathering honey from what we call the primrose, of which our prairies are white, during April and May; also from a blue blossom resembling the common sage.

This is the first year I ever knew bees to lie out in early spring; even our earliest swarms lay out for several days, but all are at work now, except some old ones in box hives which have not swarmed yet.

South Bosque, Tex., May 6, 1883.

For the American Bee Journal.

How to Read Works on Bee-Culture.

W. H. STEWART.

I have owned and handled bees, more or less, for the last 40 years, and I have read many works on bee-culture during that period. I have ever experienced a peculiar delight in seeing bees work, and in handling them; although the handling of bees 30 or 40 years ago was attended with more pain than pleasure.

I have ever found that bee-keepers were of an inquiring turn of mind. Whenever two or more of them met in conversation, some bee talk would have to be passed around, each inquiring of the other how they managed to get along with the bees and avoid mishaps and drawbacks, and, as the conversation led on, the art of bee-keeping would often be discussed in all its various ramifications (as far as then understood), and as we were about to part, I have often put a bee-book or paper in the hand of a friend, telling them, at the same time, that they would derive from it very much valuable information, if they would read it carefully.

When we met those persons again, we would inquire how they liked the books. Of course we got various answers. Some seemed much delighted, and said they had found very much valuable instruction in them. Others that seemed to view the subject at a shorter range, would say:

"I hardly know whether I like that magazine very much or not. Why, the truth is, that the more I read it, the more I got mixed, and when I had read it all through, I made up my mind that I didn't know a thing about bees, and the book didn't know half as much as I did."

Now, the truth is, that many who have made the latter answer, were men of very sound minds, but as they seemed to overlook one fact, the whole work was to them confusion. For instance, the article was, perhaps, written by an author living in Southern Ohio, who had given his experience

in bee-culture in that locality, and he would recommend to others the *modus operandi* that seemed to work well in a mild climate. The reader lived, we will say, in Northern New York or Canada, and he found that bee-culture, as laid down in the book, was just the opposite of his own experience.

During all these many years, bee-culture has become wider spread, and has also taken a higher stand, and a magazine like the AMERICAN BEE JOURNAL is found to contain letters, giving the experience of the most important bee-keepers of every State in the Union. Not only so, but of Canada, England, France, Italy, Germany, Scotland, and, in fact, all parts of the civilized world.

Now, suppose an amateur bee-keeper should read, in the BEE JOURNAL, the experience and success of a bee-keeper in Texas, who used a hive that would hold about half a bushel, and had plenty of swarms in the month of March; wintered all on the summer stands, without any other protection than a simple plain box of inch boards; and extracted honey in April.

Suppose this amateur bee-man lived in Vermont or Canada, and engaged in bee-culture on the Texas plan, he would be sure to meet failures on every hand, by overlooking the fact that bee-culture in Texas is not at all like bee-culture in any Northern climate.

On the other hand, if this beginner had discriminated between bee-culture in Texas and bee-culture as practiced by Mr. Jones, of Canada, and had been governed by the experience of the latter, he might have met with success.

Let us suppose that a man should cast anchor in Northern Wisconsin, in the month of November, with his wife and five or six robust children, and propose to let the children sleep on the ground, and himself and wife in the blanket-clad wagon, through the three or four months that he wished to remain. Suppose you remonstrate with him, and tell him of his imprudence, and he should reply that he often did in that way in Louisiana, where he came from. You might post up notices that there would be half a dozen second-class funerals at that camp within four weeks, and you would be safe in doing so.

The truth is, that all warm-blooded animals require a certain amount of warmth, or they are not in a comfortable condition. If they are not comfortable, then they cannot be healthy. Animal life is shortened up just in proportion to the ill-health of the individual. As with children and our domestic animals, even so with bees; they all need different care in different localities.

Thus, all will see, that in order to get a "portion of meat in due season," it becomes necessary that we glean from our bee paper the most important items as deduced from experiences of our own locality, and as the AMERICAN BEE JOURNAL embodies the experience of the most reliable bee-keepers of the civilized world, it is very easy for all to find

in it that which will do them good in their localities.

Then, scan we keen the A. B. JOURNAL,
Met in friendly council there;
Sisters, brothers, all fraternal,
Strength in union everywhere.
Strength in union, be our motto,
Emblem, little honey-bee;
Outward, onward, swell the echo,
Greeting, send it o'er the sea.
Orion, Wis.

Remarks on Those Big Reports.

J. L. VAN ZANDT, M. D.

In *Gleanings* of about May 1882, B. F. Carroll, of Texas, reports a remarkable queen (a hybrid Cyprian, if I mistake not), which was proving to be wonderfully prolific, filling in all four stories, 40 frames with brood. Later, in July, he reports the "largest yield" 700 lbs. of honey. Then he is called to order, stating that Mr. Somebody had previously reported 737 lbs.; in Iowa, probably. There being an abundance of rain, Mr. C.'s bees in the fall gathered 100 lbs. more and enough to winter on—after your bees, Mr. Editor, were asleep.

A great cry is raised, "4 or 5 doubled up," "yield of colony and increase," and sundry insinuations, because forsooth Mr. C., with a climate allowing his bees to gather pollen every month in the year, and honey almost as long, should report a yield of less than 9 per cent. more than an Iowa man, whose bee year is but little more than half as long.

If it is a yield of a one-story hive, and not of the immediate progeny (workers) of one queen that is to be reported, I would suggest to Mr. C. that he have a one-story hive large enough to accommodate her Royal Highness, in order that his report will "pass muster."

The writers from whom I have quoted, are all readers of *Gleanings*, so in charity I conclude that they overlooked Mr. C.'s explanation, and also the report of over 1,000 lbs. from one queen and her increase.

This is not prompted by personal friendship, as I am not acquainted with Mr. C.

Dido, Texas.

Western New York Convention.

A few of the leading bee-keepers of Western New York, held a meeting at Fredonia, April 28, 1883, and organized an Association. The day was not one calculated to make bee men buoyant, being cold and raw, with occasional gusts of snow; the hills from 2 to 4 miles south of Fredonia being shrouded with a snowy mantle, which no doubt kept many from attending. The meeting was, however, a very enthusiastic one; 8 became members by paying the membership fee of 50 cents, and the following were elected officers for the ensuing year: President—U. E. Dodge, Fredonia. Vice President—T. A. C. Everets, Randolph. Secretary—T. W. Gleason,

Fredonia. Treasurer — Miss Bessie Marsh.

It was then resolved that each member be requested to obtain others to unite with the Association, collect the fees and forward them to the Secretary.

The Secretary was instructed to prepare the minutes of the meeting for publication, and to be paid \$1 for expenses and trouble.

T. A. C. Everets made some very interesting remarks on Queen Rearing, Wintering, etc. He was not much in favor of cellar wintering; he preferred contracting the brood chamber (according to the size of the colony) with division boards, and enclosing the hives on the summer stands in an outside shell, some 4 to 6 inches longer than the hive, packing the space at the sides and on the top of the hive with dry forest leaves; he much preferred this method to cellar wintering.

E. Moon, of Moon's Station, said it was 40 years since he bought his first colony of bees, and he had more or less bees ever since, sometimes as high as 30 or 40 colonies; he has honey on his table 2 or 3 times a day, the year round, and divided liberally with the needy around him; he had never sold but 14 lbs. of honey during the 40 years he had kept bees; he had 18 good colonies last fall, but only had 3 very weak ones this spring; yet he was not discouraged; he had just bought 12 colonies, and was prepared to start anew and make bee-keeping pay; what he wanted to know was how to winter bees successfully, and advised beginners to go slow.

President Dodge spoke very favorably of cellar wintering; although he had only one year's experience in that method of wintering; if he could succeed as well every winter as he had during the past one, he could hardly ask anything better, losing only one weak colony out of 42 wintered in his cellar. He had compared closely the condition of those wintered in the cellar and those wintered on the summer stands; he thought the indications were very much in favor of cellar wintering. Speaking of hives, he said it makes but little difference what pattern we use, provided it be so constructed as to be easy of manipulation at all times, and susceptible of thorough packing and protection to the bees, with surplus arrangements both for comb and extracted honey. He would not advise bee-keepers to winter their bees all in one way; would winter some in the cellar, some on the summer stands, and, perhaps, a few colonies, each winter, in clamps. He was asked by C. E. Gates what books on bee-culture he would recommend for beginners. He replied that this was a delicate question to answer. Should he give his honest opinion, it might hit some one's corns. He had Quinby's New Bee-Keeping, Cook's Manual of the Apiary, A B C in Bee-Culture, Dzierzon's Rational Bee-Keeping, Newman's Bees and Honey, Alley's Handy Book for Bee-Keepers, etc.—all works of the highest merit. He would advise beginners to purchase one or more of these, and sub-

scribe for some good bee paper, and start with a few colonies. He thinks the Langstroth hive, for beginners, as good as any. He feeds all colonies, short of stores, with good granulated sugar syrup; he prefers it to anything except the very best sealed honey; he feeds for winter stores during the latter part of September or early in October.

J. A. Benedict, of Brocton, had made bee-keeping pay; he wintered his bees on the summer stands; sets the hives in a compact form, and builds a tight board fence around them. He would hardly like to take the chances of wintering in his cellar; thinks it is too damp. He spoke very highly of Mr. Moon's benevolence, and would be glad if there were more of such men. He thought if there were, that the world would be much better than it is now, and the needy would fare much better.

Wm. Bauling, of Dunkirk, winters his bees in the Quinby hive, packed with oat chaff; he builds a storm house over the entrances, with lath; inserts a hollow elder or sumac into this storm house, which gives plenty of air, and acts as an ear trumpet; he could put his ear to the end of this tube, which is above the snow line, any day during the winter, and hear with ease what is going on inside of the hives. He is located in the midst of 10 or 15 acres of sweet clover, and proposes to sow more; he thinks it the best substitute for basswood, where that is scarce.

On the whole, it was very pleasant and profitable meeting; a general good feeling prevailed, and the interests of apiculture seemed to take a step in advance.

Adjourned to meet May 18, at Fredonia, in T. W. Gleason's office, at 10 a. m. All interested in bee-culture are invited.

T. A. C. EVERETS, Sec.

U. E. DODGE, Pres.

Convention for Northern Iowa.

There seems to be a number of bee-keepers in the northern counties of Iowa. Why could not a meeting be held at some central point on the C. M. & St. P. R'y.? How many vote aye?

J. G. BENNETT.

Emmetsburg, Iowa, April 27, 1883.

There will be a meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association on Tuesday, May 15, 1883, at Mr. E. Whitteley's, two miles south of Pecatonica, Winnebago County, Ill.

J. STEWART, Sec.

Rock City, Stephenson County, Ill.

Quite a number of the new subscribers, who have begun to take the JOURNAL this month, ask if we can supply the numbers from Jan. 1, 1883. We would say that we can supply a few more sets, and if any want them they must be sent for soon, or they cannot be obtained. We can supply no more numbers of 1882. They are all gone.

SELECTIONS FROM OUR LETTER BOX

How Bees Wintered in New York.

My 156 colonies of bees were wintered in the cellar, and came out in fine condition. In cellar No. 1, 155 were wintered with the loss of one nucleus; in cellar No. 2, 118, with the loss of one colony, which starved. The prospects for a good honey season were never better in this county, if the weather becomes favorable. Bees have had but little chance to fly yet; it has been so cold and windy. They are working finely, to-day, on the soft maples and willows. In the central part of this county there is only about one colony of bees now, where there were three one year ago.

IRA BARBER.

De Kalb Junction, N. Y., May 8, 1883.

The Season in California.

Through sickness last season, I lost most of my bees, after extracting 2,500 pounds of good honey. I saved only 10 pure Italian queens; I bought some blacks, and now have, with increase of 16 swarms, 39 colonies of Italians, to-day. I have to extract, this week, to keep down swarming. Young queens have been laying a week or ten days. The weather is cool at nights, and we have late spring rains. The honey crop is not very encouraging. The rain fall is light. The mountain streams have only been full once this season. Most of the time there has been but very little more water running than through the summer; that is, where the streams run the year through. Late rains have revived the flowers. Bees have made a living and a little more. It is too cool for comb honey.

J. D. ENAS.

Napa, Cal., April 23, 1883.

The Old Foggy Bee-Keeper.

I am not an expert in the art of bee-keeping, by any means, but I have a neighbor living about one-half mile from my place, who, seeing what I had done, last summer, with my bees, thinking, I suppose, to get rich, has embarked in the business. When visiting, I would tell some little experience that I had from working with my bees, and what I had learned from the BEE JOURNAL and Cook's Manual, etc.; it seems natural for bee-keepers to talk and tell all they know of the art. I tried to get him to take the BEE JOURNAL. I told him if he would take the JOURNAL I would send the order with mine and he could have the premium, Bees and Honey, in cloth. He took home some of my JOURNALS to read. Next time I saw him, I asked if he was going to take the JOURNAL? He said, No; he did not believe one word of it; he did not want it; but I see he has lost one or two colonies of bees this spring, besides lots of brood, trying to build up weak colonies. In such cold weather the brood would get chilled, before

this master of the art could do what he did not believe men of 20 years experience was doing right. Of course I do not wish him bad luck; that is not my make-up; I would rather see him do well and make money, if there is money in it, but when a man tells me he does not believe what men of experience says, it makes me feel sorry for the bees that he may own. I shall not talk with him any more about bees. I like to be told what I do not know, and I do not think that I shall ever get so much experience but that some one can tell me something.

E. L. FRIEDENBURG.
Fentonville, Mich., May 9, 1883.

Something New to Me.

On the first day of May, I was called upon by a party three miles from my residence, to transfer 2 colonies of black bees. In transferring, I found them collecting honey, building combs in four boxes, and storing honey in the boxes; this is unusual in this vicinity. Out of 108 colonies of bees, which I put into winter quarters last fall (36 in cellar, and 72 on the summer stands), I lost one in the cellar. I think it was queenless, and, therefore, died. The rest came out very strong, with from 4 to 8 frames of brood, and a few about ready for the boxes. Of those on the summer stands, I lost four, principally by spring dwindling, three being somewhat weak, leaving me 100 colonies in fine condition. I lost eight in all. I like cellar wintering best, thus far.

DANIEL WHITMER.

South Bend, Ind., May 12, 1883.

Spring Dwindling.
